1.0 INTRODUCTION

This report presents the results of Harding Lawson Associates' (HLA) preliminary soil characterization investigation at the Oakland Broadway Block, Chinatown Redevelopment Project Area, 9th Street and Broadway, Oakland, California (site; Plate 1). The soil characterization was performed on behalf of and under contract to the Redevelopment Agency of the City of Oakland (Agency).

The site comprises the area bounded by Broadway, 9th Street, and Franklin Street, and the southern edge of the Transpacific Building. The site developer, Pacific Renaissance Associates (PRA II), plans to construct a high-rise building onsite. Before construction begins, the Agency wishes to assess whether soil contamination is present at the site, to minimize the potential for human exposure and construction delays during excavation and construction of the building's foundation and basement. Approximately 30,000 cubic yards of soil will be excavated from the site, assuming excavation to a depth of 15 feet.

1.1 Background

The site is currently an asphalt covered parking lot. The Agency has investigated previous uses of the site; these include but may not be limited to printing shops, paint supply dealers, a battery shop, a garage, a laundry, and a janitorial supply distributor. According to the Agency, most of these businesses operated for 5 years or less, except for the laundry and garage which operated for periods of 40 to 50 years. The former locations of known businesses and their years of operation are shown on Plate 1.

The Bay Area Rapid Transit District (BART) KAL and KAR lines traverse the site (Plate 1). The top of the shallower of the two tunnels is approximately 17 feet below ground surface (bgs).

A groundwater monitoring program is currently underway in the Chinatown Redevelopment Project Area. This area is bounded by Broadway, 9th, 11th, and Webster Streets. As part of groundwater monitoring in this area, two groundwater monitoring wells were installed at the site (Wells MW-20, MW-21) and a third near the site (Well MW-7). The wells are approximately 35 feet deep. Soil samples from the borings for MW-20 and MW-21 were screened for petroleum hydrocarbons using an organic vapor analyzer (OVA) and selected samples were submitted for laboratory analysis. Neither the OVA screening nor laboratory analysis indicated the presence of volatile organic compounds (VOCs) or petroleum hydrocarbons in unsaturated soil (*HLA, 1990a, b*).

During construction at the Pacific Renaissance Plaza (PRP) building east of the site, two underground storage tanks were discovered beneath the sidewalk on the east side of Franklin Street (Plate 1). Petroleum hydrocarbon contaminated soil was observed to extend beyond the PRP excavation toward the site. These observations were considered in selecting sample locations, depth, and analytes to assess subsurface conditions at the site and to assess whether petroleum hydrocarbons originating from the former tank location at the PRP site may have affected the subsurface at the site.

1.2 Purpose and Scope

The purpose of the soil characterization investigation was to:

- Characterize the nature and extent of contamination in site soil, from the near surface (fill and soil under the asphalt paving and baserock of the parking lot) to approximately 30 feet bgs. A depth of 30 feet was

selected as a practical limit of characterization because of the constraints imposed by the BART tunnels on the design of any future building.

- Estimate the volume of soil that would require special handling or disposal during excavation, and assess disposal options.

The soil characterization investigation comprised the following tasks:

- Preparing a work plan and job safety plan
- Obtaining permits from the Alameda County Flood Control and Water Conservation District (ACFCWCD) Zone 7, and BART
- Contracting a California-licensed surveyor to survey and mark the BART KAL line centerline, structural limits, and right-of-way
- Clearing boring locations using nonintrusive geophysical techniques and Underground Service Alert
- Assessing the possible presence of buried tanks using geophysical *✓ Only in soil locations.* techniques.
- Drilling and collecting soil samples from 27 soil borings
- Selecting and analyzing soil samples based upon field observations and the historical uses of the site
- Arranging for the disposal of the soil cuttings from the borings
- Evaluating the field and analytical data and preparing this report.

1.3 Organization of This Report

The report is organized as follows. Section 2.0 describes the acquisition of required permits, field investigation techniques, sampling methods, and laboratory analyses. Section 3.0 describes the site geology, groundwater, and the nature and extent of the chemical compounds detected in the subsurface. Section 4.0 presents conclusions regarding the investigation and estimates of the volumes of soil affected by the chemical compounds which may be encountered during construction. Copies of permits, laboratory reports, sample custody documents, and a description of geophysical

procedures are included in the appendices. Limitations of the report and references used in preparing it are presented in Sections 5.0 and 6.0, respectively.

2.0 FIELD INVESTIGATION AND LABORATORY ANALYSIS

2.1 Permitting and Preparing for Soil Boring Installation

On October 14, 1992, HLA submitted a Request for Encroachment Permit to BART to drill soil borings within the BART subsurface easement; this easement is associated with tunnels and does not extend to ground surface. BART issued the Encroachment Permit to HLA on December 31, 1992. On December 30, 1992, the ACFCWCD issued Drilling Permit #92671 to HLA for the proposed borings. Copies of the permits are in Appendix A.

HLA contacted Underground Service Alert on January 11, 1993, to request that public and private agencies, utilities, and companies that have underground service and utility lines in or near the site mark their services and lines. On January 11 and 12, 1993, the BART KAL line centerline, limit of structure, and right-of-way were painted on the asphalt paving by Geotopo Inc. (surveyors), Oakland, California; these features are shown on Plate 1. On January 12, 1993, HLA used nonintrusive geophysical techniques at each boring location to identify buried utilities or obstacles prior to drilling.

2.2 Soil Boring and Sampling

Between January 19 and 22, 1993, Borings 1 through 17 were drilled onsite. After completion of a geophysical survey on April 23 and 24, 1993, to locate any USTs onsite, 10 additional borings (Borings 18 through 27) were drilled on May 13, 1993. Boring locations are shown on Plate 1. Three borings were drilled within the BART subsurface easement; Borings 6, 12, and 13 were drilled to 15 feet bgs. Borings 19 through 22 were drilled to 3.5 feet bgs; these borings were within the footprint of the BART easement (projected to the surface) but did not encroach on the easement.

Borings 1 through 5, 7, 9 through 11, and 14 through 17 were located outside of the BART subsurface easement and were drilled to 26.5 or 30 feet bgs. Boring 8 was stopped at 7 feet bgs by an obstruction. Borings 18 and 27 were drilled near anomalies detected in the geophysical survey to depths of 16.5 and 25.5 feet, respectively. Borings 23 through 26 were shallow (5.5 feet) borings drilled in a cluster near Boring 17 on the southern boundary of the site to evaluate metals concentrations.

The borings were drilled by Gregg Drilling & Testing, Inc., Pacheco, California, using a truck mounted drill rig equipped with 6-inch-diameter, hollow-stem augers. Soil samples were collected at 5-foot intervals using a 2.0-inch-outside diameter, split-barrel sampler equipped with three clean, 1.5-inch-diameter, 6-inch-long, stainless steel sample tubes. The soil sample tubes were capped with Teflon-lined plastic caps, labeled, sealed in plastic bags, and refrigerated for transport to the analytical laboratory.

The borings were descriptively logged by an HLA field geologist. The soil was classified in accordance with ASTM Method D2488-90. The boring logs are presented on Plates 3 through 25; a summary of the soil classification system is presented on Plate 26. The soil samples were screened in the field using an organic vapor analyzer (OVA), and by visual inspection for soil staining. OVA readings, odor, and soil staining are noted on the boring logs.

Following completion, each boring was backfilled by pumping a lean cement/bentonite grout through a tremmie pipe from the bottom of the boring to the ground surface. Soil cuttings were temporarily stored onsite in a locked soil bin. Following receipt of the soil sample analytical results, the soil was disposed at McKittrick Waste Treatment Site, McKittrick, California.

2.3 Selection of Soil Samples for Analyses

Soil samples were collected at approximately 5-foot intervals from each boring for lithologic description. Samples suspected of containing petroleum hydrocarbons were retained for organic compounds analyses. The samples analyzed for metals were selected on the basis of historical site uses and were concentrated in shallow soil (1.0 to 5.0 feet bgs) from areas where former businesses, such as the battery or print shops, may have released chemicals to the environment (Plate 1). To provide for areal distribution of soil samples and for confirmation purposes, additional samples were also selected and analyzed from areas and depths where soil contamination was not observed or suspected.

2.4 Soil Sample Analytical Program

Soil samples were submitted under chain of custody to NET Pacific Laboratories, Inc. (NET), Santa Rosa, California, to be analyzed for total petroleum hydrocarbons as diesel (TPHd), TPH as gasoline (TPHg), benzene, toluene, ethylbenzene, and total xylenes (BTEX), VOCs, semivolatile organic compounds (SOCs), and priority pollutant metals. NET is a California-certified laboratory for the analyses requested. Copies of the laboratory reports and the chain of custody forms are presented in Appendix B.

2.5 Groundwater Sampling and Analysis

Groundwater samples were collected from the three wells at and near the site to evaluate groundwater chemistry at the site and whether potential sources of petroleum hydrocarbons have affected groundwater. On June 24, 1993, groundwater samples were collected from Monitoring Wells MW-7, MW-20, and MW-21 (Plate 1); these wells were originally installed as part of a groundwater monitoring network for the adjacent PRP project site.

Depth to water was measured in each well prior to sampling. Three well volumes were purged from each well, collected in 55-gallon drums and retained onsite. Groundwater samples were collected using a stainless steel bailer and decanted into 40-milliliter sample containers which were labeled and stored on ice until delivery under chain of custody to the analytical laboratory. Samples were submitted to Pace Laboratories, Inc. (PACE), Novato, California, to be analyzed for TPHg using EPA Test Method 8015, and BTEX using EPA Test Method 8020. PACE is a state-certified laboratory for the analyses requested. Copies of laboratory reports, chain of custody documents and well sampling forms are included in Appendix B.

2.6 Equipment Decontamination

To minimize the possibility of cross contamination, all downhole drilling and sampling equipment was decontaminated before use. The augers and well development and sampling equipment were steam cleaned before drilling. The soil sampling equipment was washed in a low-phosphorus soap solution and rinsed with deionized water before sampling. Decontamination rinsate was temporarily stored onsite in sealed 55-gallon drums until receipt of laboratory analytical results, at which time it was appropriately disposed.

2.7 Geophysical Survey

To locate USTs at or near the site, HLA performed a geophysical survey April 22 and 23, 1993. Electromagnetic profiling (EM), ground penetrating radar (GPR), and two types of pipe and cable locators (RD400 and M-Scope) were used. The survey identified eight anomalies; two were associated with areas within the site boundary where historical uses and experience at other sites in the Chinatown Redevelopment

Project Area suggest that tanks, vaults, or similar objects might be present. These two areas were further investigated by drilling Borings 18 and 27. A description of the geophysical survey is presented in Appendix C.

3.0 RESULTS

3.1 Site Lithology

Review of the soil boring logs indicate that the site is underlain by fill consisting of clayey gravel with sand to depths up to 4.5 feet, and dark yellowish brown and dark brown silty sands from below the fill to at least 30 feet bgs, the maximum depth explored. During drilling, water-saturated soil was encountered at depths ranging from 22.5 to 27.5 feet bgs.

3.2 Analytical Results for Soil Samples

Comparison of the analytical results with the location and depth of the soil samples does not indicate the presence of priority pollutant metals above estimated background concentrations or the presence of organic compounds in most site soil. Three zones of soil having elevated concentrations of organic compounds or priority pollutant metals have been identified. Two of these areas are in shallow soil; one contains organic compounds and the other contains lead and zinc. The third is an area of soil at a depth of 25 feet bgs which is affected by petroleum hydrocarbons. Areas are shown on Plate 2.

3.2.1 Organic Compounds in Shallow Soil

Twenty-two soil samples from depths of 10 feet or less were analyzed for organic compounds. TPHd was detected in 13 of these shallow soil samples (Table 1, Plate 2). The sample from Boring 6 at 1.5 feet bgs contained 1,600 mg/kg TPHd. All other shallow samples contained less than 100 mg/kg TPHd. The analytical laboratory reported that the TPHd detected in the 1.5-foot samples from Borings 19 through 22 appeared to be due to the presence of hydrocarbons heavier than diesel. None of the shallow samples contained TPHg or BTEX compounds. Four of the samples also

contained low concentrations of tetrachloroethene (PCE). Samples from 1.5 to 5.0 feet bgs in Borings 6, 17, 19, and 20 contained PCE at concentrations between 0.0026 and 0.022 mg/kg.

3.2.2 Lead and Zinc in Shallow Soil

Twenty-one shallow soil samples were analyzed for priority pollutant metals (Tables 2 and 3). One of the 21 soil samples contained zinc at an elevated concentration of 17,000 mg/kg (Boring 17 at 5.0 feet bgs). All other detected priority pollutant metals were at concentrations below the average metal concentrations in soil for the San Francisco Bay area (*Shacklette and Boerngen, 1984*). However, two of the samples contained lead at concentrations considerably higher than in other samples from the site. The sample from Boring 6 at 1.5 feet bgs contained 230 mg/kg lead and the sample from Boring 17 at 5.0 feet bgs contained 320 mg/kg lead. The zinc concentration from the sample in Boring 17 at 5.0 feet bgs exceeds the total threshold limit concentration (TTLC, *California Code of Regulations Title 22, Chapter 11, Article 3*) for zinc.

3.2.3 Petroleum Hydrocarbons in Deeper Soil

Petroleum hydrocarbons, including TPHd, TPHg, and the BTEX components, were detected in soil samples collected from Borings 11, 15, 17, and 27 at 24.5 to 25 feet bgs. These borings were drilled along the southern edge of the site (Plate 2). Concentrations of TPHd ranged from 470 to 1,000 mg/kg, concentrations of TPHg ranged from 350 to 2,000 mg/kg, and concentrations of BTEX components ranged from nondetect to 15 mg/kg total xylenes. The sample from Boring 15 contained minor amounts of the SOCs 2-methylnaphthalene and naphthalene (Table 1).

Analysis of soil samples from Borings 17 and 27 reported TPHd to be present. However, review of the analytical chromatograms by chemists at NET and HLA

indicated that the chromatograms are not characteristic of diesel and may represent hydrocarbons lighter than diesel.

No petroleum hydrocarbons were detected in the 25-foot samples from Borings 3, 4, 10, or 16, or in the 20-foot samples from Borings 2, 11, 15, or 27. Similarly, no petroleum hydrocarbons were detected in unsaturated soil samples from borings for Wells MW-20 and MW-21 (*HLA, 1990b*).

3.3 Nature and Extent of Chemicals in Groundwater

No petroleum hydrocarbons or BTEX compounds were detected in groundwater samples from Wells MW-7, MW-20, and MW-21 collected on June 24, 1993.

3.4 Potential for Presence of Buried Objects

The geophysical survey results (Appendix C) indicate several anomalies within site boundaries or near the site. At two of these locations within the site, where historical uses and experience in the Chinatown Redevelopment Project Area indicate that tanks or vaults may be present, borings (18 and 27) were completed to investigate the presence of tanks and the potential for release. Results did not confirm the presence of tanks and did not identify the presence of chemicals indicative of release from the vicinity of the anomalies investigated.

3.5 Discussion

Occurrences of TPHd in shallow soil are primarily at depths of 2 feet and less, suggesting that diesel may have been discharged at the surface or may have been associated with fill used to bring the ground surface to grade after building demolition and prior to construction of the parking lot. If fill was used in this manner, there may be additional areas containing diesel. The volume of shallow soil containing TPHd at

concentrations less than 100 mg/kg is estimated to be approximately 1,500 cubic yards.

The volume of shallow soil containing TPH as diesel at concentrations greater than 100 mg/kg is estimated to be less than 20 cubic yards.

On the basis of data collected to date, the volume of shallow soil containing elevated concentrations of lead is estimated to be less than 30 cubic yards. Of this 30 cubic yards, it is estimated that less than 15 cubic yards also contain elevated concentrations of zinc.

The TPH pattern at the 25-foot depth near the southern boundary of the site suggests a source in this area. The petroleum hydrocarbons detected at 25 feet bgs appear to have originated from an unknown source along 9th Street and spread horizontally away from this source on the water table within the area bounded by Borings 10 and 16 and Monitoring Well MW-21. Geophysical survey results indicate the presence of an object that may be a tank within the release footprint and near the southern boundary of the site. No additional investigations have been undertaken to assess the nature of this object. Based on the data available, the volume of soil at this depth containing petroleum hydrocarbons is estimated to be 900 cubic yards.

*Unknown source
could be the BART
back fill*

4.0 CONCLUSIONS AND RECOMMENDATIONS

With the following exceptions, the analytical results for soil samples did not show the presence of organic chemicals, or of inorganic chemicals above normal background levels for soil from the San Francisco Bay Area:

- Shallow soil near Boring 6 shows elevated concentrations of lead and concentrations of TPHd greater than 100 mg/kg. About 20 cubic yards of soil at this location is expected to require disposal at a Class I or Class II landfill.
- Approximately 1,500 cubic yards of shallow soil showing concentrations of TPHd below 100 mg/kg should be acceptable for disposal at a Class III landfill.
- Shallow soil near Boring 17 shows elevated concentrations of lead and zinc. An estimated 15 cubic yards of soil at this location may require disposal at a Class I landfill.
- An estimated 900 cubic yards of soil within the site boundary at a depth of 25 feet bgs contains petroleum hydrocarbons. If excavated, these soils are expected to require disposal at a Class II landfill.

The distribution of petroleum hydrocarbons in soil at 25 feet bgs suggests that the petroleum hydrocarbons extend offsite beneath 9th Street (Plate 2).

During construction, the excavation subcontractor should be prepared to safely handle and dispose of soil containing petroleum hydrocarbons and metals. Soil containing elevated concentrations of analytes should be segregated for appropriate disposal. Excavation activities in the vicinity of the detected analytes should be observed by a geologist to evaluate the distribution of affected soil.

Because of the limited nature of the boring program implemented to explore the geophysical anomalies, it is possible that buried objects which could be tanks or vaults are present within site boundaries. Although there is no direct evidence of the presence of tanks or vaults, or of release from them, the presence of such objects and associated releases should be considered in planning for excavation. For the two anomalies

investigated with borings, it is recommended that the possible presence of buried objects be confirmed using direct exploration methods such as trenching prior to the start of excavation. Completing exploration for and removal of any tanks found prior to the start of excavation will minimize the potential for delays once construction commences.

5.0 LIMITATIONS

The conclusions and recommendations presented in this report are professional opinions based on the indicated data described in this report. They are intended only for the purpose, site location, and project indicated. It should be recognized that this study was not intended to be a definitive study of all environmental conditions at the site and that other contaminants not analyzed during this study may be present, although HLA has no reason to believe that such may be the case. Interpretations presented on maps are only accurate at the specific points where samples were collected and/or chemically analyzed. The data presented between these points are interpretations and therefore subject to change as additional information becomes available.

Conclusions presented herein apply to site conditions existing at the time of our study. They cannot apply to site changes of which HLA is not aware and has not had the opportunity to evaluate. Changes in hazardous waste management standards can also occur as the result of legislation or from the broadening of knowledge. Accordingly, the findings of this report may be invalidated, wholly or in part, by changes beyond our control.

HLA's services have been performed with the same degree of care, skill, and diligence normally provided by qualified and reputable professional persons performing services similar to those performed on this project.

7 ND<1 = not detected at indicated reporting limit

8 ND = not detected; see laboratory analytical reports for reporting limits of individual analytes

9 Tetrachloroethene detected at this concentration. No other analytes were detected. See laboratory analytical reports for reporting limits of individual analytes.

10 The analytical laboratory report indicates that the result for TPH as diesel appears to be due to the presence of hydrocarbons lighter than diesel.

11 The analytical laboratory report indicates that the result for TPH as diesel appears to be due to the presence of hydrocarbons heavier than diesel.

MW-21	24-Jun-93	ND/ND	ND/ND	ND/ND	ND/ND	ND/NT

Notes:

Results reported in milligrams per liter (mg/l); equivalent to parts per million.

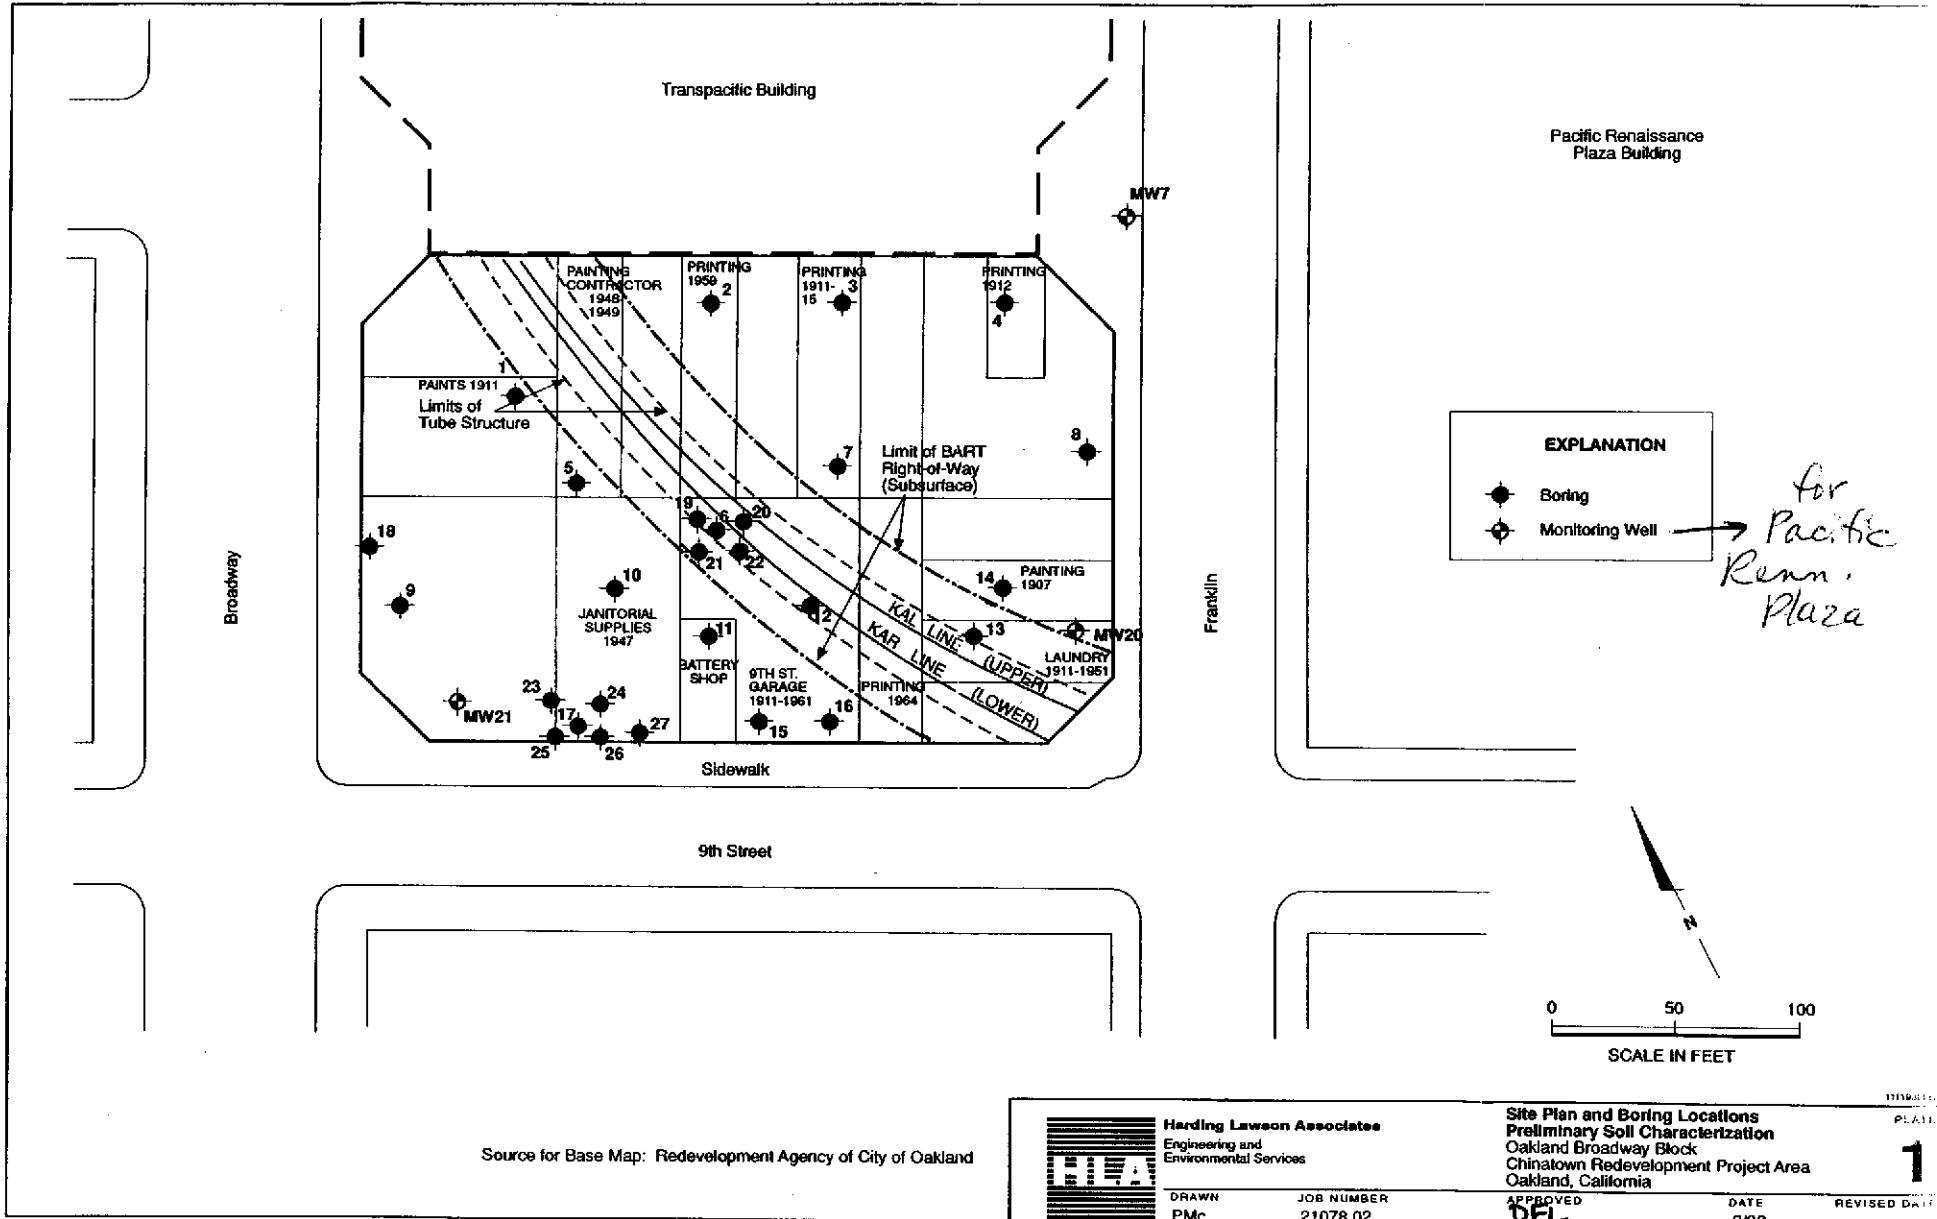

Analyses performed by PACE Laboratories, Inc., Novato, California.

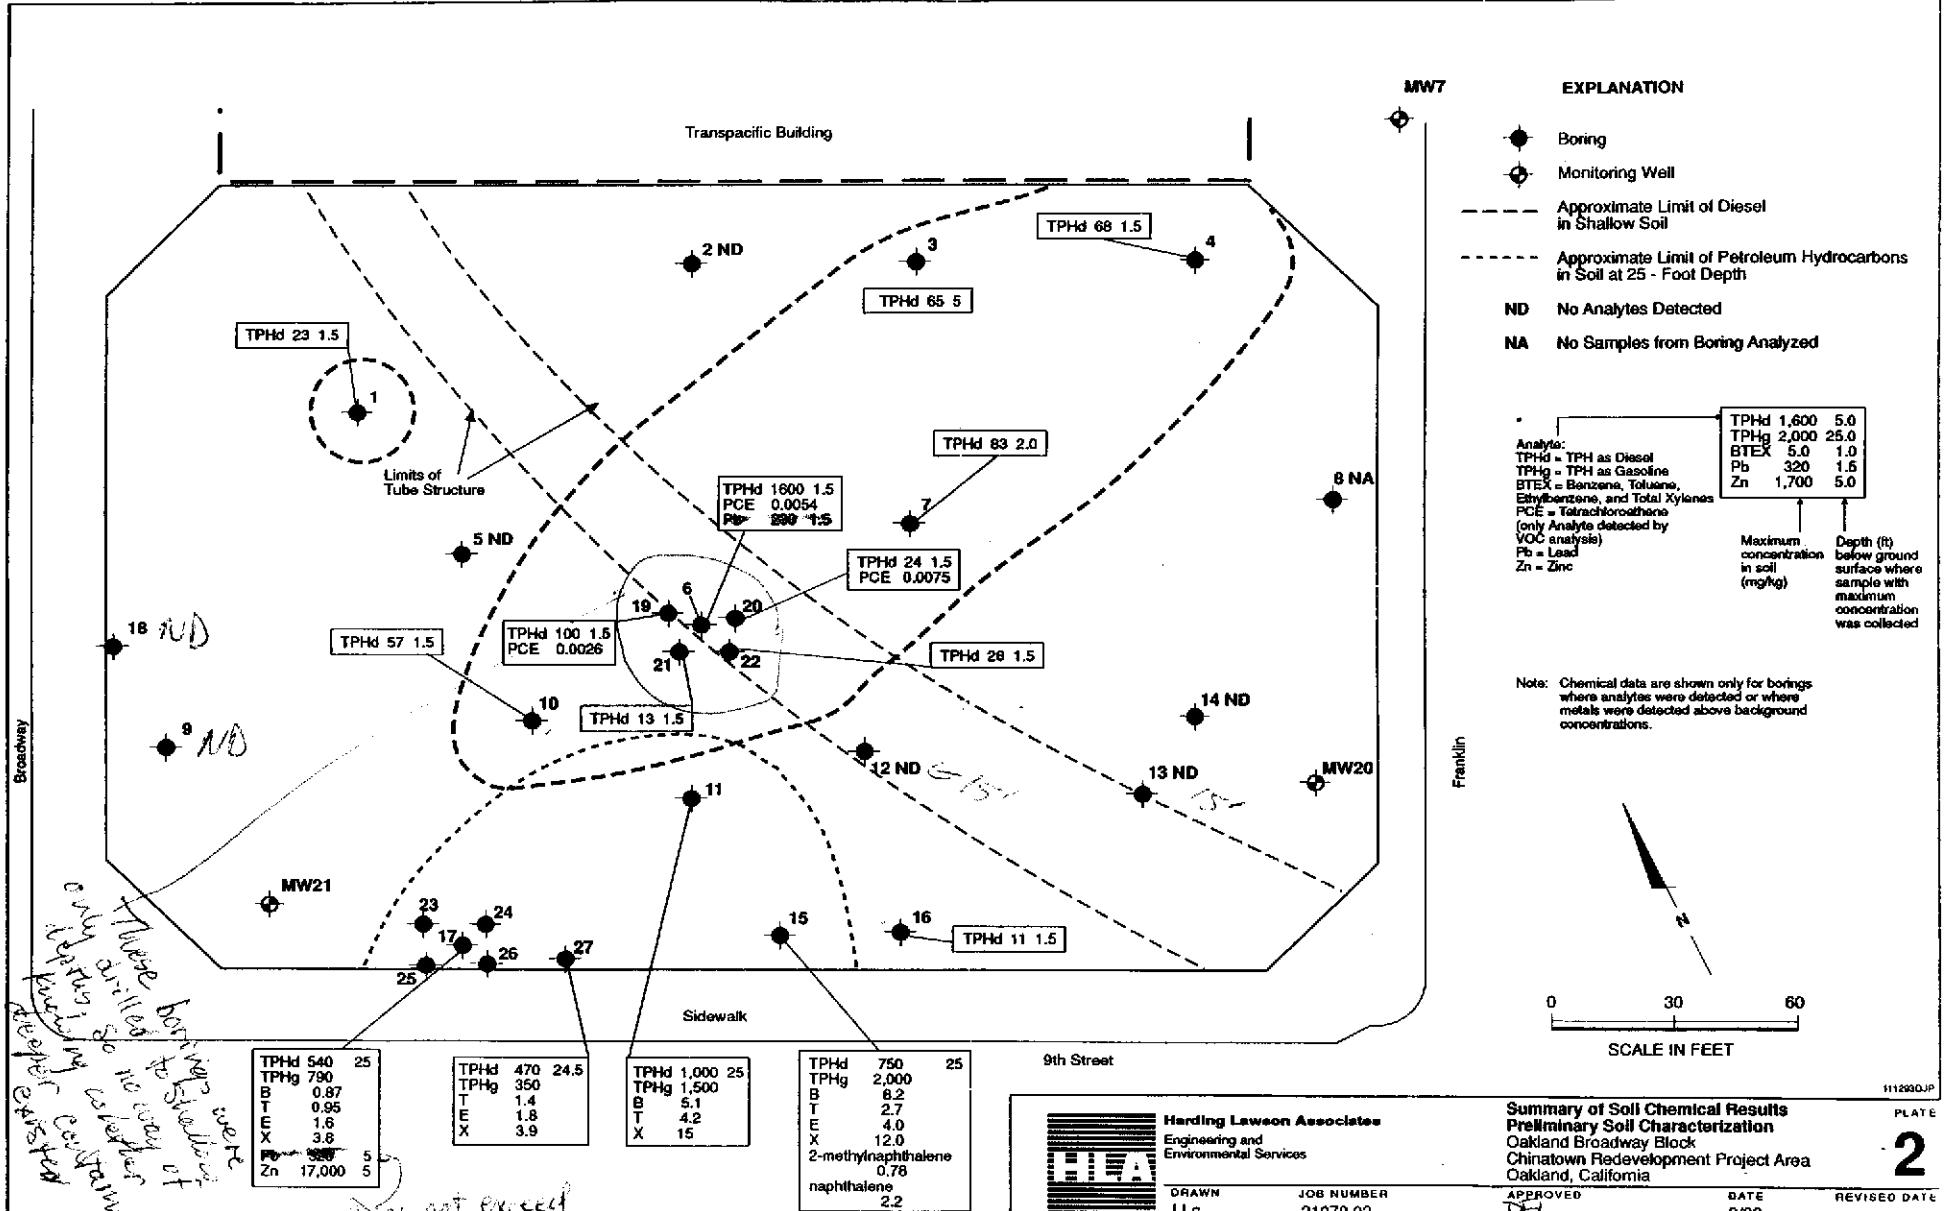

Two values indicate results of duplicate analyses.

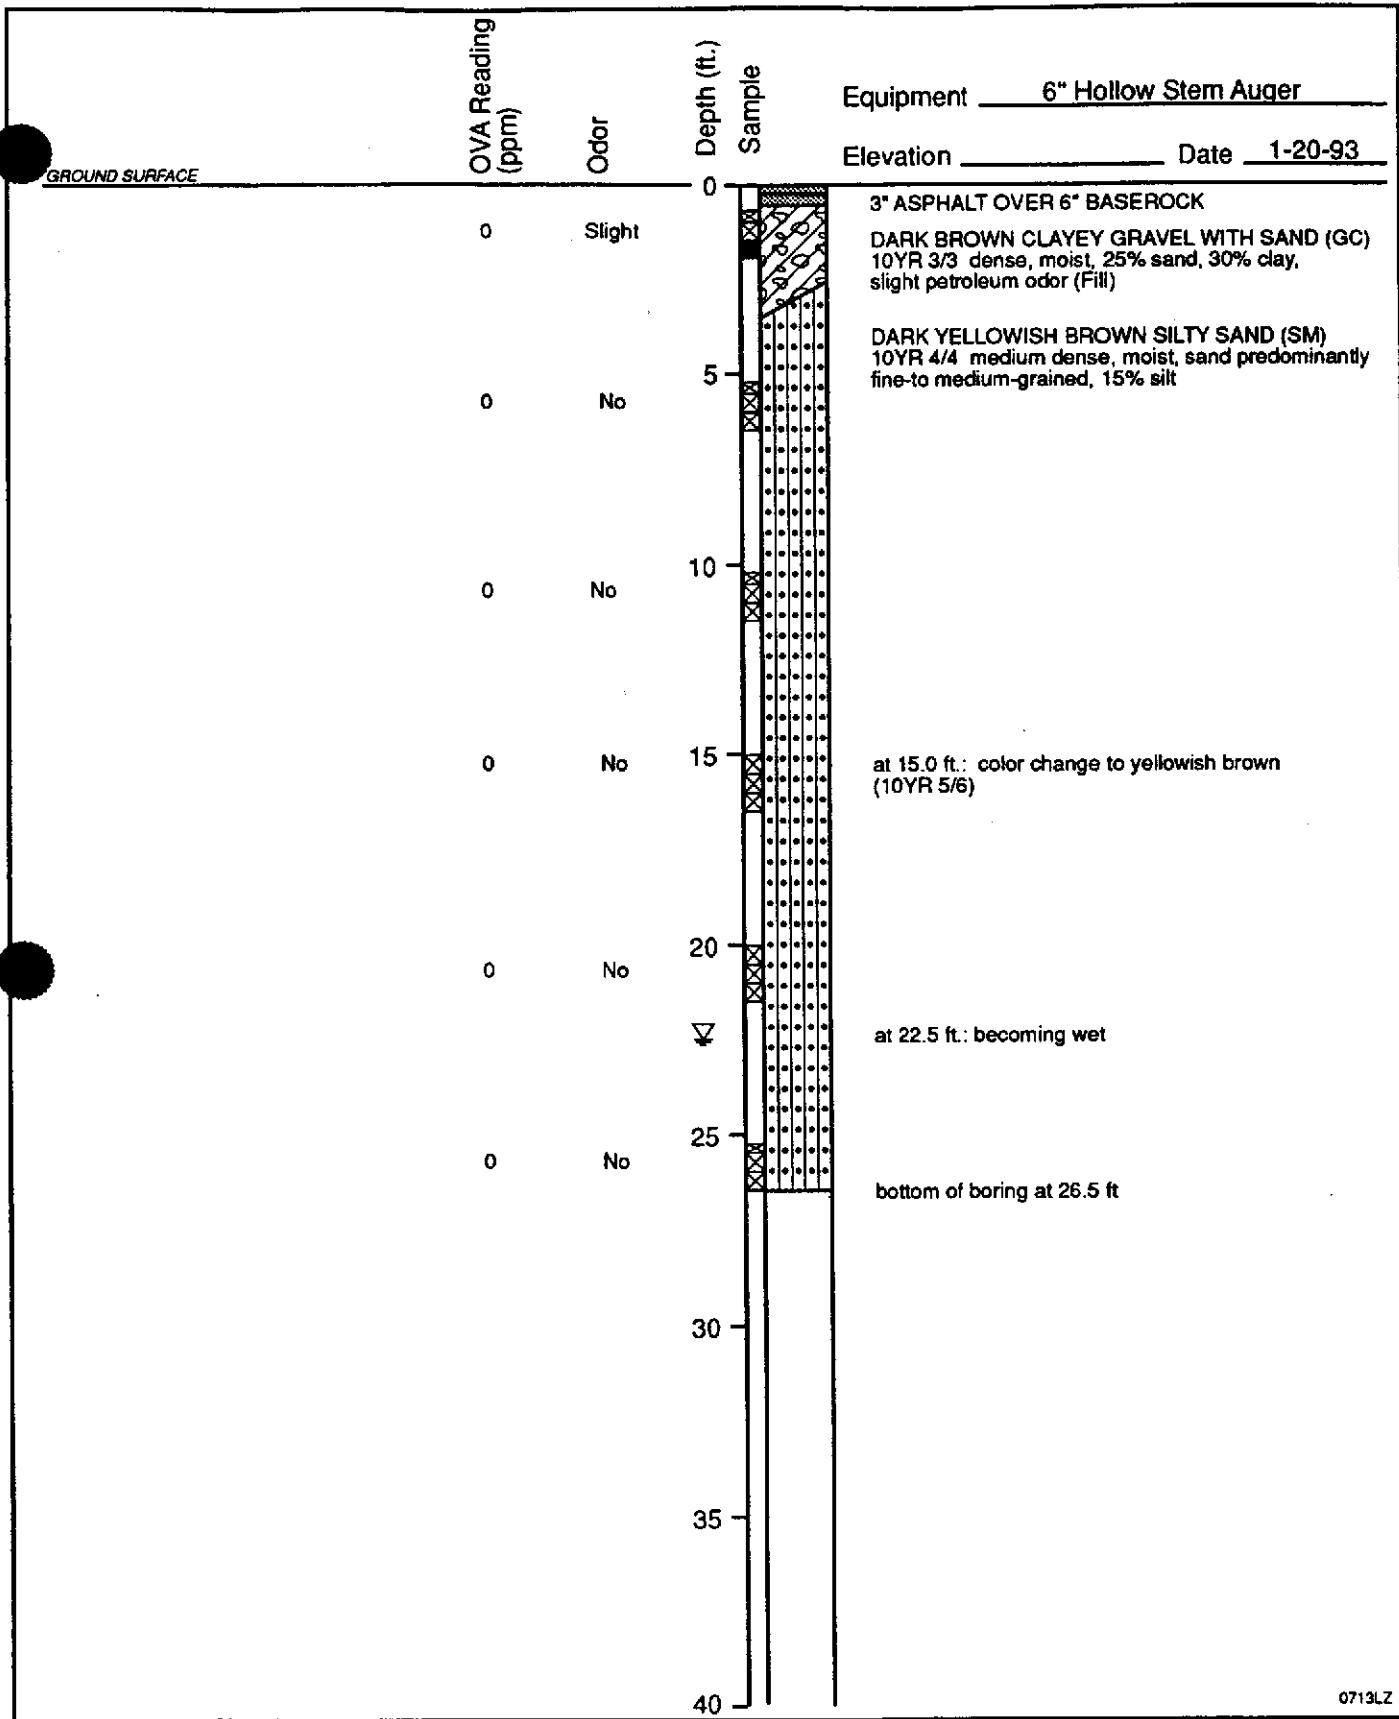

LOD: Limit of Detection.

ND: Not detected at or above LOD.

NT: Not tested.

The San Francisco Bay Area Rapid Transit District (BART) has reviewed your October 14, 1992 request for an encroachment permit to drill three soil borings within the BART subsurface easement at the above project location.

Permission to drill, as set forth in your letter, is approved subject to the following conditions:

- (1) BART shall be indemnified from all liabilities associated with the drilling activity or resulting from any hazardous waste or toxic substances discovered during the boring operations.
- (2) BART shall be named as an additional insured on the insurance policies of the Redevelopment Agency and the contractor. The current amount of insurance is \$1,000,000 for each entity and shall be maintained during the performance of the work.
- (3) At least 14 calendar days prior to the beginning of any boring or construction activities, please contact Chris Koukis, Maintenance Coordinating Engineer, at (510) 464-6445, who will coordinate your plans with the District.
- (4) Prior to any boring or construction activity, the limits of BART subsurface easement and tunnel shall be surveyed and marked on the ground.

I have enclosed a copy of BART's "General Guidelines for Design and Construction Over or Adjacent to BART Subway Structures" for your use and guidance.

Mr. David Leland, Harding Lawson Assoc.
December 21, 1992

Page 2

Please have an authorized person sign the acceptance block below and return to my attention together with certificates of insurance.

Incidentally, the ownership shown on plate 1 is incorrect in that the Redevelopment Agency is the fee owner of Parcels A, B, and C with BART holding only a subsurface easement interest in B.

If you have any questions, please feel free to call me at (510) 464-6161.

Sincerely,

Robert W. Zickwolf
Real Estate Engineer

Title _____

SAN FRANCISCO BAY AREA RAPID TRANSIT DISTRICT

GENERAL GUIDELINES
FOR
DESIGN AND CONSTRUCTION OVER OR ADJACENT
TO BART SUBWAY STRUCTURES

1. Zone of influence is defined as the area above a line from subway invert at a slope of 1-1/2 horizontal to 1 vertical.
2. Soil redistributions caused by temporary shoring or permanent foundation system shall be analyzed.
3. Shoring shall be required to maintain soil's at-rest condition. Shoring structure shall be monitored for movement.
4. Minimum predrilled depth for piles shall be approximately 10 feet below the line of influence.
5. Vibration monitoring of piling operations closest to subway will be required. Piles to be driven in a sequence away from the subway structure.
6. Tunnels, where affected, shall be monitored for movement and deformation due to adjacent construction activities as to ensure structural and operational safety.
7. Dewatering shall be monitored for changes in groundwater level. Recharge program will be required if existing groundwater level is expected to drop more than 2 feet.
8. Minimum clearance between any part of adjacent structure to existing exterior face of subway structure shall be 7'-6". No pile will be allowed between tunnels.
9. Minimum cover of 8 feet shall be maintained over existing subway structures wherever possible.
10. Structural and crack surveys shall be accomplished in a timely manner before, during and after construction.
11. Design loads above cut and cover subways are as follows:
 - a) Where the depth of cover (the vertical distance from the top of the subway roof to the ground surface) exceeds 20 feet, the subway structure is generally designed to support only the weight of the earth cover, and no additional surface load can be permitted without consideration of the specific design proposed.

- b) Where the depth of cover is from 5 feet to 20 feet, the structure is designed to support the weight of earth cover plus a vertical surcharge load computed from the following formula: $L = 800 + 40d$; where L is the surcharge load in pounds per square foot and d is the depth of cover in feet.
- c) Where the depth of cover is less than 5 feet, the design load is computed from the depth of earth cover plus a vertical surcharge of 600 pounds per square foot.

12. Design loads over shallow tunneled subways are as follows:

The circular tunneled subways are designed to support the weight of 35 feet of earth above the roof of the tunnel. Wherever the actual depth of cover is less than this amount, construction may be added imposing an additional average vertical loading of 120 pounds per square foot for each foot of depth of reduced cover.

- 13. Loads in excess of the above shall not be imposed on the existing subway structure under any circumstances. Where basements are excavated, the amount of loading can be increased to the extent that it is balanced by the weight of the removed material (120 pounds per square foot for dry soil, and 70 pounds per square foot for submerged soil). However, the effects of soil rebound in such cases shall be fully analyzed.
- 14. All structures shall be so designed as not to impose any temporary or permanent adverse effects, including unbalanced loading and seismic loading, on the adjacent BART subways.
- 15. Design of underground storage tanks for flammable and combustible liquids shall conform to the requirements of Article 3-2.7 of NFPA 130 of the National Fire Codes.
- 16. The above should be considered as general information only and is not intended to cover all situations. Individual conditions may vary widely, and it is not possible to apply simple criteria that will adequately cover all possible loading conditions which might be imposed on the subway structures. For this reason, the District needs to review and approve design plans for each construction proposal.

ALAMEDA COUNTY FLOOD CONTROL AND WATER CONSERVATION DISTRICT

5997 PARKSIDE DRIVE • PLEASANTON, CALIFORNIA 94588 • (510) 484-2600

JAN 4 '93 AM10:08

Novato, California Zip 94945 or X6769

A. GENERAL

1. A permit application should be submitted so as to arrive at the Zone 7 office five days prior to proposed starting date.
2. Submit to Zone 7 within 60 days after completion of permitted work the original Department of Water Resources Water Well Drillers Report or equivalent for well Projects, or drilling logs and location sketch for geotechnical projects.
3. Permit is void if project not begun within 90 days of approval date.

B. WATER WELLS, INCLUDING PIEZOMETERS

1. Minimum surface seal thickness is two inches of cement grout placed by tremie.
2. Minimum seal depth is 50 feet for municipal and industrial wells or 20 feet for domestic and irrigation wells unless a lesser depth is specially approved. Minimum seal depth for monitoring wells is the maximum depth practicable or 20 feet.

- C. GEOTECHNICAL. Backfill bore hole with compacted cuttings or heavy bentonite and upper two feet with compacted material. In areas of known or suspected contamination, tremied cement grout shall be used in place of compacted cuttings.

- D. CATHODIC. Fill hole above anode zone with concrete placed by tremie.

E. WELL DESTRUCTION. See attached.

COMMENT: Blank Results were ND on other analytes tested.

KEY TO ABBREVIATIONS and METHOD REFERENCES

- : Less than; When appearing in results column indicates analyte not detected at the value following. This datum supercedes the listed Reporting Limit.
 - * : Reporting Limits are a function of the dilution factor for any given sample. To obtain the actual reporting limits for this sample, multiply the stated Reporting Limits by the dilution factor (but do not multiply reported values).
- ICVS : Initial Calibration Verification Standard (External Standard).
- mean : Average; sum of measurements divided by number of measurements.
- mg/Kg (ppm) : Concentration in units of milligrams of analyte per kilogram of sample, wet-weight basis (parts per million).
- mg/L : Concentration in units of milligrams of analyte per liter of sample.
- mL/L/hr : Milliliters per liter per hour.
- MPN/100 mL : Most probable number of bacteria per one hundred milliliters of sample.
- N/A : Not applicable.
- NA : Not analyzed.
- ND : Not detected; the analyte concentration is less than applicable listed reporting limit.
- NTU : Nephelometric turbidity units.
- RPD : Relative percent difference, $100 \times \frac{\text{Value 1} - \text{Value 2}}{\text{mean value}}$.
- SNA : Standard not available.
- ug/Kg (ppb) : Concentration in units of micrograms of analyte per kilogram of sample, wet-weight basis (parts per billion).
- ug/L : Concentration in units of micrograms of analyte per liter of sample.
- umhos/cm : Micromhos per centimeter.

KEY TO ABBREVIATIONS and METHOD REFERENCES

:	Less than; When appearing in results column indicates analyte not detected at the value following. This datum supercedes the listed Reporting Limit.
*	: Reporting Limits are a function of the dilution factor for any given sample. To obtain the actual reporting limits for this sample, multiply the stated Reporting Limits by the dilution factor (but do not multiply reported values).
ICVS	: Initial Calibration Verification Standard (External Standard).
mean	: Average; sum of measurements divided by number of measurements.
mg/Kg (ppm)	: Concentration in units of milligrams of analyte per kilogram of sample, wet-weight basis (parts per million).
mg/L	: Concentration in units of milligrams of analyte per liter of sample.
mL/L/hr	: Milliliters per liter per hour.
MPN/100 mL	: Most probable number of bacteria per one hundred milliliters of sample.
N/A	: Not applicable.
NA	: Not analyzed.
ND	: Not detected; the analyte concentration is less than applicable listed reporting limit.
NTU	: Nephelometric turbidity units.
RPD	: Relative percent difference, $100 \frac{[Value\ 1 - Value\ 2]}{mean\ value}$.
SNA	: Standard not available.
ug/Kg (ppb)	: Concentration in units of micrograms of analyte per kilogram of sample, wet-weight basis (parts per billion).
ug/L	: Concentration in units of micrograms of analyte per liter of sample.
umhos/cm	: Micromhos per centimeter.

APPENDIX C
GEOPHYSICAL SURVEY

GEOPHYSICAL SURVEY

INTRODUCTION

The objective of the survey was to detect, to the extent possible, the location, size, and orientation of potential buried underground storage tanks (USTs). The area covered by our investigation was a strip approximately 30 feet wide that paralleled the curbs of Broadway, 9th, and Franklin Streets. The geophysical survey was performed on April 22 and 23, 1993, by HLA geophysicists Thomas A. Casebier and J. Scott Lewis.

GEOPHYSICAL METHODS

A combination of methods was used for the UST search, including electromagnetic profiling (EM), ground penetrating radar (GPR), and two types of pipe and cable locators (RD-400 and M-Scope).

Electromagnetic Profiling

The EM technique entails transmitting a primary signal that is inductively coupled to the earth. Secondary signals are generated in the ground, and both the primary and secondary fields are detected by the EM receiver. The EM system is also susceptible to the presence of buried conductors, including both ferrous and non-ferrous metals. Metal objects such as steel USTs are electrically conductive compared to native soil and therefore produce anomalous readings in conductivity values. A Geonics Ltd. Model EM31-D electromagnetic terrain conductivity system was used in this investigation. The in-phase mode of the EM31-D is particularly sensitive to buried metal objects. The system is limited to a depth of approximately 20 feet and is not effective within approximately 20 feet of surface metal structures or vehicles.

Ground Penetrating Radar

The GPR system uses radar technology to obtain a continuous high-resolution electromagnetic profile of the subsurface. The depth of penetration is a function of the electrical conductivity properties of the subsurface materials and the radar antenna frequency. GPR transmits a signal that is coupled to the ground by an antenna. When the subsurface signal encounters a boundary between media of different electrical properties, such as that between a buried tank and overlying soil, some of the energy is reflected back to the surface, received by the antenna, amplified, and displayed on a monitor. A traverse along a GPR scan line results in a continuous graphic profile record of the subsurface. A GSSI Model SIR-7 system and a 500-MHz antenna were used to acquire the GPR data. The depth of investigation for the GPR was approximately 6 feet at the site.

Pipe and Cable Locators

The Fisher Model TW-6 M-Scope is an electromagnetic system similar in principle to the EM31-D but is susceptible only to buried metal objects and pipes. The M-Scope is comprised of separate modular transmitter and receiver connected by a carrying handle. It can resolve smaller metal objects than the EM31-D. The M-Scope is effective to depths of approximately 4 to 5 feet and within approximately 8 feet of surface metal.

The Radio Detection Corporation RD-400 consists of a separate transmitter and receiver. Two types of signals can be passively detected: those resulting from electrically powered lines and those associated with metal pipes that re-radiate ambient radio signals. In the active mode, the transmitter generates an 8- or 33-KHz signal that can either be inductively coupled to subsurface pipes or cables, or directly connected to

pipes or cables that extend to the surface. The resulting signals may then be traced on the surface by the receiver.

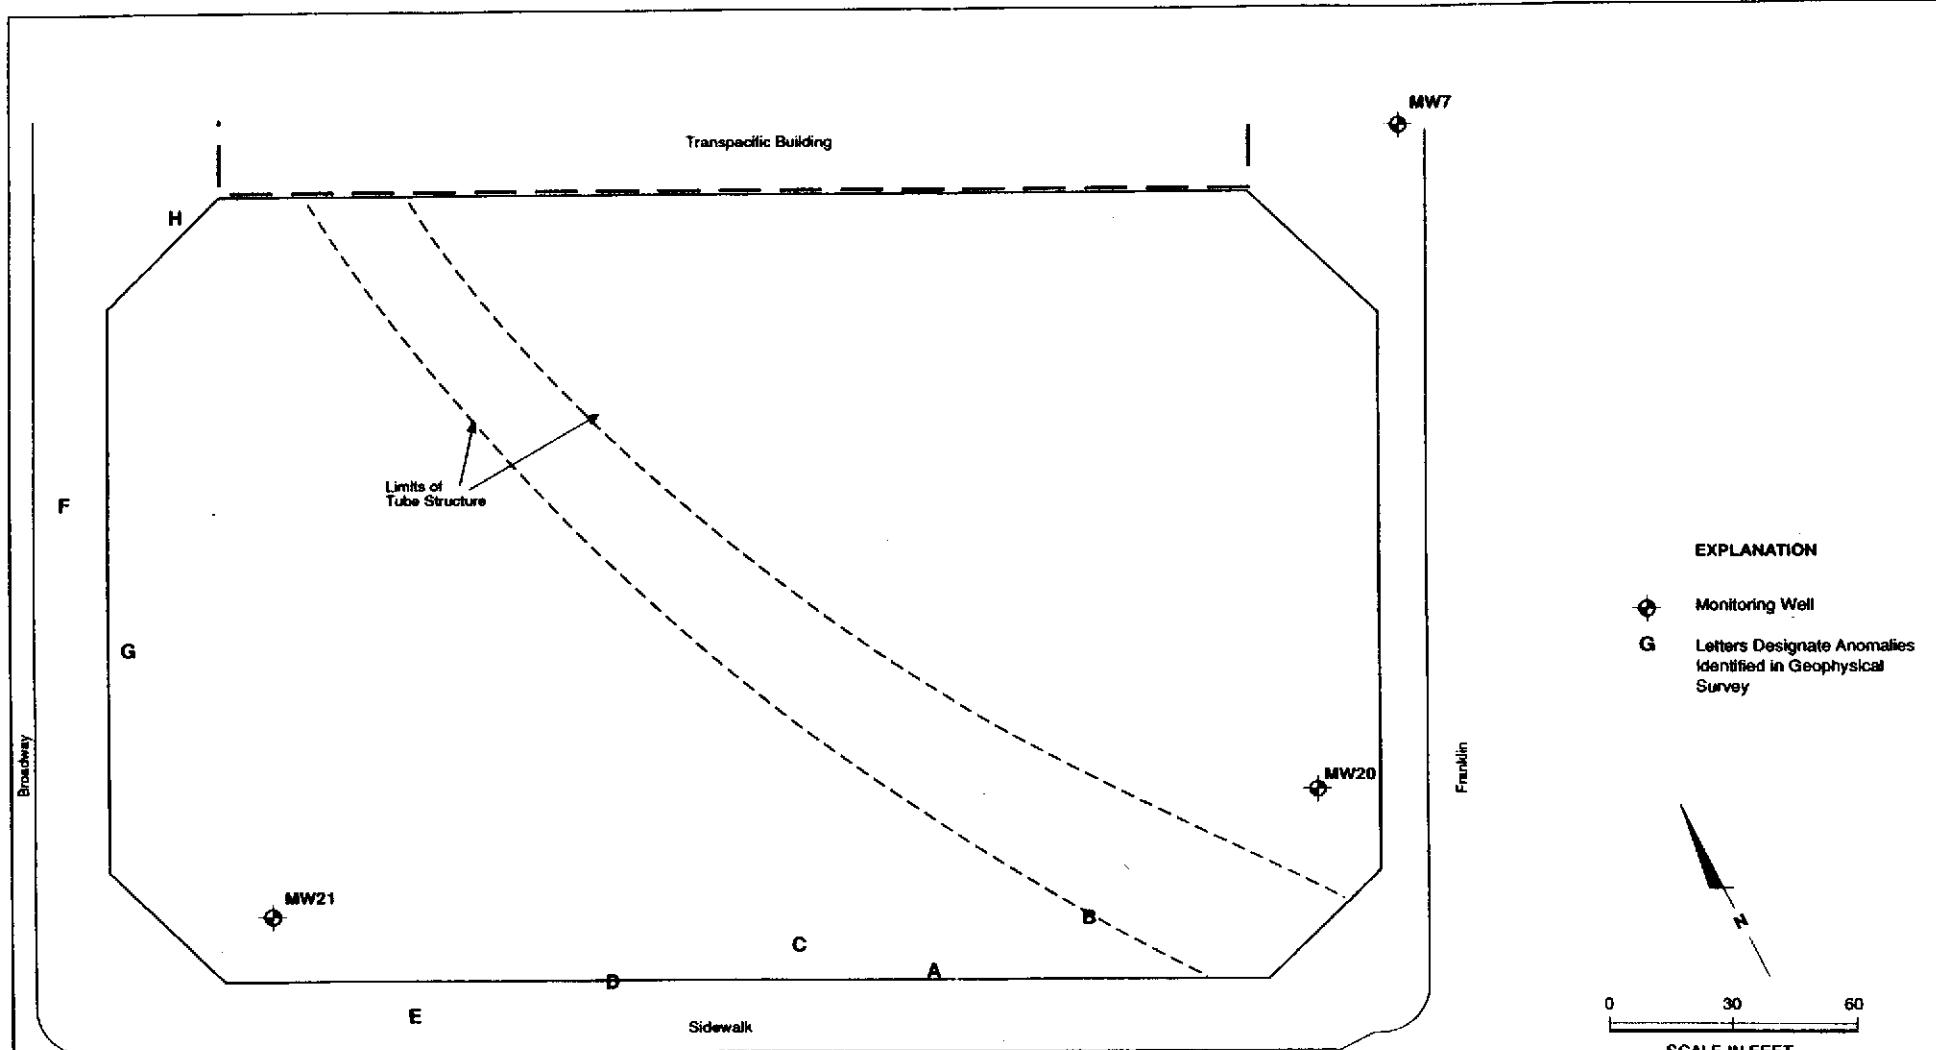

FIELD PROCEDURES

Field work was coordinated with Mr. Robert Nelson, HLA geologist. After a review of site conditions and a discussion with Mr. Nelson, the following tasks were performed:

1. Barricades and caution tape were used to close off the parking spaces of the eastern half off the site and adjacent to the wall separating the sidewalk and the parking lot.
2. The EM31-D system was used to perform a reconnaissance of the site on lines spaced 5 feet apart. The instrument was operated to monitor both conductivity and in-phase (mode susceptible to metal) signals to search for anomalous signals indicative of large masses of buried metal. Anomalous areas were marked using spray paint on the ground surface.
3. The M-Scope was used to perform a reconnaissance of the site using procedures similar to the EM-31D.
4. GPR was used to generate continuous graphical profiles of the subsurface on lines spaced 5 feet apart and parallel to the curbs. Both 300- and 500-MHz antennas were pulled by hand along all profiles.
5. The RD-400 receiver was used to trace buried utilities. The locations of all detected utilities were marked on the surface with lumber crayon. These locations were then eliminated from consideration as possible UST locations.
6. A site field sketch was generated that included prominent surface features, detected EM and M-Scope anomalies, and detected buried utilities.
7. Tasks 1 through 5 were repeated for the western half of the site on day 2 of the field survey.
8. Boring locations were cleared to avoid buried utilities and other subsurface obstructions in the areas determined to be potential UST locations.

FINDINGS

The EM and M-Scope reconnaissance detected eight localized anomalous areas, labeled A through H, indicative of possible buried metal. GPR profiles extending across the anomalous areas detected no discernable USTs within approximately 5 feet of the surface. An UST buried deeper than 5 feet may not have been detected by GPR. GPR data quality was good due to the moderate conductivity (less than 100 millimhos/meter for the upper 20 feet) of local soil and low conductivity of the upper 5 feet of clean fill. Five of the anomalous areas, A, C, D, E, and G, are recommended for further investigation by potholing, borings, or other direct methods. No other anomalous areas were detected that could not be attributed to buried utilities.
