Mr. Don Parker Vintage Properties/Alameda Commercial 1150 Marina Village Parkway Alameda, California 94501

Subject: Report Detailing Excavation of Petroleum-Affected Soils from the Field Area South of the Powerhouse, Alameda Marina Village, Alameda, California.

#### Dear Don:

Enclosed please find the subject report detailing excavation, soil sampling procedures, chemical analysis results, waste characterization and data interpretation.

Diesel-affected soils within an area of approximately 6,300 square yards, with a thickness of about one foot, were excavated from the subject site. The total volume of soils excavated was approximately 5,000 cubic yards.

Laboratory analyses of soil samples collected from the excavation bottom indicate that the petroleum-affected soils have been sufficiently removed from the area, to the extent that no further remediation of the soils should be required.

Fuel identification analyses indicated that several types of fuels were present in the soils, predominantly diesel fuels (#2 and #6) and smaller amounts of heavier oils.

The excavated soils, stockpiled on a vacant lot south of Tyson Street, were tested to assess their average concentration of petroleum hydrocarbons. The soils contained 85 to 370 parts per million (ppm) total petroleum hydrocarbons (TPH), averaging about 200 ppm. These concentrations are above the RWQCB guidelines of 100 ppm TPH for disposal at a Class III landfill.

Two underground fuel storage tanks were removed from the site, and disposed of with a hazardous waste manifest. These tanks had apparently been in the ground for at least 45 years, as indicated by a 1943 Sanborn map of the area. When encountered, the tanks

1900 Powell Street, 12th Floor Emeryville, California 94608 (415) 652-4500

were found to contain #2 diesel fuel. There was evidence that leakage from one of the tanks had occurred into surrounding soils.

Besides the apparent underground tank leakage of #2 diesel fuel, sources of other fuels encountered in the soil were not distinguishable, based either on field evidence or laboratory data. It is assumed that the other, heavier fuels were introduced to the site decades ago when previous industrial facilities were active at and in the vicinity of the site.

Although no further remediation requirements are anticipated for the site, it is likely that ground-water quality monitoring will be required.

If you have any questions, comments, or would like to request any modifications to the report, please contact the undersigned at your earliest convenience.

Sincerely,

Tom Graf, P.E. Principal Engineer Elizabeth Nixon Project Engineer

# REMOVAL OF PETROLEUM-AFFECTED SOILS FROM THE FIELD AREA SOUTH OF THE POWERHOUSE ALAMEDA MARINA VILLAGE Alameda, California

#### 1.0 INTRODUCTION

This report describes excavation activities conducted June 9 through 24 and September 9, 1988, and tank removal activities performed July 26, 1988 in the field area south of the Powerhouse ("the Site"). The area is located southwest of Marina Village Parkway and north of Tyson Street in Alameda Marina Village in Alameda, California (Figure 1).

## 1.1 Background

A previous investigation conducted in March 1988 by Levine Fricke revealed the presence of an approximately 1-foot thick interval of petroleum-affected soils in the field area south of the power-house. An area of approximately 5,550 square yards (sy) near the water table (6 to 12 feet below ground surface) was affected. The petroleum was identified by a specialty fuel identification laboratory as a degraded diesel fuel. Total petroleum hydrocarbon (TPH) concentrations in the soils ranged from 70 to 13,000 parts per million (ppm).

Water-quality data gathered from the sampling of shallow ground-water monitoring wells (installed in the field area as part of the investigation) indicated that the petroleum-affected soils have had only a minor impact on site ground-water quality. Of two wells located within the affected area, a ground-water sample from one well contained 1.8 ppm TPH, while the other well did not contain detectable concentrations of TPH. Neither well contained detectable concentrations of benzene, toluene, xylenes, or ethylbenzene (BTXE). Of three ground-water monitoring wells 50 to 250 feet northwest and west of the affected area, a ground-water sample from only one well contained very low concentrations of BTXE (less than 1 ppb of toluene and ethylbenzene, and 3 ppb of xylenes). Otherwise, there were no detectable concentrations of TPH or BTXE in ground-water samples from these wells.

Results of this investigation were reported in Levine Fricke's April 25, 1988 draft report to Vintage Properties/Alameda Commercial.

## 1.2 Summary of Recently-Completed Work

Vintage Properties/Alameda Commercial chose to remove the petroleum-affected soils from the field area to reduce the potential for future environmental liabilities at the site.

Approximately 5,000 cubic yards (cy) of soil were removed during excavation activities. Excavated soils were stockpiled on an engineered surface at an adjacent property on the south side of Tyson Road, south of the field area (Figure 2). Sampling and chemical analyses of these soils indicated that their TPH concentrations ranged between 87 and 370 ppm, averaging approximately 200 ppm.

A redwood-box tunnel containing utility pipes and two underground fuel storage tanks containing diesel fuel were encountered in the field area during excavation activities. The redwood box and piping were removed during excavation. The wood from the tunnel was stockpiled with the excavated soils. The pipes were disposed of as scrap metal by local metal recyclers (these had apparently been used as water pipes, as indicated on a 1943 Sanborn map). The tanks and their contents were removed after appropriate county and city permits had been obtained; they were manifested and transported to an appropriate receiving facility.

#### 2.0 SITE SETTING

#### 2.1 Geology

Subsurface soils consisted of approximately 5 to 10 feet of brown, silty, sandy and/or gravelly clay fill with variable amounts of large rocks and debris (wood, brick, concrete and asphalt). These materials were underlain by green-grey sand, silty to clayey sand, and sandy and silty clay fill containing variable amounts of shell and wood fragments. The water table was approximately 6 to 12 feet below ground surface, and generally corresponded to 1 to 2 feet below the bottom of the brown fill.

## 2.2 Subsurface Structures

The location of the redwood-box tunnel and pipes (one 10-inch, one 8-inch, and one 6-inch diameter) is shown on Figure 2. This pipe tunnel was situated at approximately the depth of ground water and was supported by concrete boxes about every 50 feet. The 1943 Sanborn map of that area shows the tunnel and pipes to be part of the facilities located there at that time. The extension of the tunnel and/or pipes beyond the area excavated, as illustrated on the Sanborn map, is partially shown on Figure 2. The present condition or existence of these pipes outside the

field area is not fully known, but it is likely that portions of the pipes were removed during redevelopment of the site over the last several years.

Numerous other pipes or segments of pipes were encountered during the excavation work. Several 2- to 4-inch-diameter pipes, oriented approximately parallel to the railroad tracks, were located close to the eastern edge of the excavation at about the depth of ground water. These pipes were removed during excavation work and, as they did not appear to have carried fuel, were collected by local recyclers as scrap metal. Segments of a deteriorated 18-inch-diameter corrugated drainage culvert running obliquely crossed the site were encountered, as shown on Figure 2. Petroleum hydrocarbons had accumulated in the pipe, so it was removed and stockpiled with the petroleum-affected soils.

The locations of the two underground storage tanks encountered in the field area are shown on Figure 2. The 1943 Sanborn map indicates that these tanks, one 1,500-gallon capacity (Tank 1), and one 2,400-gallon capacity (Tank 2), were used to store fuel oil. Both tanks contained #2 Diesel fuel when they were encountered. The design of the larger tank (described below) suggested that it had been used at one time to store fuel heavier than #2 Diesel. The smaller tank had not been designed for heavier fuels.

## 2.3 Distribution of Petroleum-Affected Soils

The black petroleum-stained sediments were contained within the normally green-gray sandy fill material at ground-water depth. The highly-weathered product appeared to be generally immobile, except in a few areas where pockets of product had accumulated, and near one of the underground storage tanks where product appeared less weathered.

Petroleum-affected soils were somewhat discontinuous throughout The thickest areas of the area and of variable thicknesses. staining (1 to 2 feet thick) were located in the central portion near the wooden tunnel and drainage culvert, and in the southwest central portion near the 1,500-gallon capacity fuel oil tank. Near soil sample location 5 (see Figure 2), an apparently isolated pocket of very viscous, dark product was encountered seeping from the excavation sidewall. The product was identified as resembling a Bunker C fuel (see Fuel Fingerprinting Analysis, The oily material appeared to have accumulated in Section 6.0). the drainage culvert located in that area. Concentrated pockets of oily sediments inside and around this culvert continued intermittently for about 50 feet on either side. Near the edges of the affected area, the petroleum staining became very thin and discontinuous and generally pinched out.

## 3.0 FIELD AREA PETROLEUM-AFFECTED SOILS

#### 3.1 Excavation

Excavation activities were performed by Fanfa, Inc. of San Lorenzo, California on June 9 through June 24, 1988. On September 9, 1988, a small additional area was excavated by O.C. Jones of Oakland, after initial chemical analyses data indicated that a small quantity of petroleum-affected soils had not been removed during the initial excavation work. (This area is represented by the sampling locations 46, 47, and 49 on Figure 2.) Either a Levine Fricke field engineer or geologist was on-site during excavation activities to observe the removal of petroleum-affected soils.

Excavation boundaries are shown in Figure 2. Approximately 6 to 10 feet of petroleum-free soils overlying the petroleum-affected layer were removed by excavation scrapers. When soils that appeared stained or oily were encountered, an excavator dug these out and loaded them into dump trucks for transport to the prepared stockpile area. The excavated area was then backfilled with the upper, clean fill. The excavation proceeded in sections, so that upper fill removed to expose the petroleum-affected soils was used to backfill an adjacent area where the petroleum-affected soils had already been excavated. Excavating and backfilling in this manner prevented the accumulation of ground water in the excavation area.

The stockpile area was prepared by compacting the top 6 inches of existing soil (by wheel-rolling) and surrounding this area with an earthen berm. Ten-millimeter-thick plastic sheeting was placed on top of the prepared surface. After the soils were stockpiled, a 5-foot high perimeter fence was installed to restrict access to the pile.

## 3.2 Soil Sampling

Soil samples were collected from the bottom of the excavated area to document removal of petroleum-affected soils. One sample (PHF16) was collected from the sidewall of the excavation adjacent to the wooden tunnel, on the western boundary of the excavation area. Locations of soil samples which were chemically analyzed are shown on Figure 2. Samples were collected in clean brass tubes, capped with aluminum foil and plastic caps, secured with electrical tape, and labeled. The samples were then placed in a cooled ice-chest for transportation to a laboratory for chemical analyses.

### 3.3 Laboratory Analyses

Twenty-six soil samples were analyzed for TPH using EPA Method 8015 (extraction) to assess whether petroleum-affected soils had been adequately removed. Laboratory analyses were performed by Brown and Caldwell Laboratories, of Emeryville; Med-Tox Associates of Pleasant Hill; and NET Pacific of Santa Rosa.

Twenty-three of these samples represent soils collected from the boundaries of the excavation. Results indicate that residual concentrations of TPH in the remaining soils are generally non-detectable, although one sample (PHF45) contained 60 ppm. Analysis results for these samples are listed on Table 1.

The remaining three soil samples (PHF14, PHF27, and PHF35/36) were collected from soils which were later excavated and added to the stockpile. Sample PHF27 was collected near the 1,500-gallon capacity fuel tank to assess TPH concentrations. Analysis results indicate that 1,400 ppm of diesel were present in these soils. Sample PHF35/36 was a composite analyzed to evaluate concentrations in the soils near the southeastern boundary of the excavation. Analysis results indicated that these soils contained 94 ppm TPH. Sample PHF14, near the northeastern excavation boundary, contained 980 ppm TPH. Soils in this area were excavated on September 9, 1988. Samples PHF46, PHF47 and PHF49 are representative of the soils which remain in this part of the excavation.

Laboratory certificates for all analyses are attached in Appendix A. (Sample identifications on the data sheets are PHF1 through PHF49).

#### 4.0 STOCKPILE CHARACTERIZATION

After the excavated soils were stockpiled and spread evenly over the prepared area, their chemical characterization was completed to assist in evaluating disposal/remediation alternatives. Characterization included the collection and laboratory analysis of twenty-eight soil samples from the stockpile.

Sample locations were spaced evenly across the stockpile. A backhoe was used to dig several feet under the surface of the pile to collect samples. Samples were collected in brass tubes, capped with aluminum foil and plastic caps, secured with electrical tape and stored in a chilled cooler for transportation to the analytical laboratory (Med-Tox Associates of Pleasant Hill).

Laboratory analyses were performed on fourteen composited samples for TPH (extraction). Additionally, four samples were analyzed for benzene, toluene, xylenes, and ethylbenzene (BTXE). Analysis

results indicate that TPH concentrations range between 85 and 370 ppm, with an average of about 200 ppm. Toluene was present in the four samples at concentrations of 0.013 to 0.018 ppm. Concentrations of benzene, xylene and ethylbenzene were not detectable. Tables 2A and 2B summarize this data.

Laboratory certificates of these analyses are included in Appendix A. (Sample identifications on the data sheets are PHFSP1 through PHFSP28).

It is presently anticipated that these soils will be bioremediated on an adjacent parcel of land owned by Vintage Properties. Discussions on this subject are currently being conducted with the RWQCB.

## 5.0 UNDERGROUND TANK REMOVAL

2 tanks 6-12 ft down

Two underground tanks were exposed during the field area excavation activities between June 9 and 24, 1988. Their locations are shown on Figure 2.

A 1,500-gallon capacity tank, located within the boundary of the petroleum-affected soils, was about half-full of water with a floating diesel layer several inches thick. The fluid level appeared to be roughly the same as the surrounding ground water. A thin, oily surface-sheen was present on the ground water surrounding the tank. Visual observations of soils surrounding the tank indicated that product had spilled or leaked from the tank.

The location of the second tank, about 30 feet outside (south) the boundaries of the petroleum-affected soils, was identified by inspection of a 1943 Sanborn map. Soils overlying the tank were excavated to expose the top of the tank. The ground-water level was at about the middle of the tank. The tank was filled nearly to the top with product, whose level was above the surrounding ground-water, indicating that little, if any, fuel had leaked from this tank.

Subsequent removal of the two tanks was postponed until the appropriate county and city tank removal permits could be obtained. Consequent tank removal procedures and soil sampling locations, methods and chemical analyses are described below.

#### 5.1 Tank Excavation

The two underground tanks were removed by Tank Excavators of Santa Cruz on July 26, 1988. A representative from the Alameda Fire Department (AFD) was present during the removals and soil sampling. The Alameda County Environmental Health Department (ACEHD), although notified of the removal, did not attend. A

This office was not at fank removal.

Levine Fricke engineer was on-site to observe the removals and to collect soil samples from the tank excavations.

Observations were made during removal activities regarding tank integrity, evidence of leakage, and occurrence of chemicals in the soils. Soil samples were collected from the edges of the excavation at the depth of the ground water (both tanks were submersed approximately half-way below ground-water level). A ground-water sample was collected from the 1,500-gallon capacity tank excavation. A ground-water sample was not collected from the 2,400-gallon capacity tank excavation, as limited spillage of the fuel during removal activities prevented representative sampling.

### 5.2 Tank Stabilization Procedures

The tanks were rendered inert by purging the remaining fluid from them (approximately 3,500 gallons from both tanks) and inserting dry ice to remove organic vapors and oxygen from the tanks. Explosivity meter readings in the tanks at least one hour after the dry ice was inserted indicated that vapor concentrations were below the Lower Explosive Limit (LEL) of 20 percent.

## 5.3 Tank and Tank Contents Disposal

Fuel and water contained in the tanks were pumped into a vacuum truck and transported with a hazardous waste manifest by H&H Ship Services to their receiving facility in San Francisco. The tanks were also transported with a hazardous waste manifest by H&H Ship Services to the same receiving facility. Copies of the manifests are included in Appendix B.

## 5.4 Tank Inspection and Field Observations

After the tanks had been emptied and excavated, they were visually inspected. Descriptions of each tank are provided below.

#### Tank 1

The 1,500-gallon capacity tank was constructed of steel with welded seams. The tank had a 3-inch by 1-inch hole at a seam on the bottom of the south end but otherwise appeared to be in good condition. Appurtenant piping was not attached to the tank.

As mentioned above, evidence of leakage or spillage from the tank was observed in the surrounding ground-water and soils.

#### Tank 2

The 2,400-gallon tank was constructed of steel with riveted seams and was fitted with a heating element on the west end. The west

end was also fitted with a bolted plate containing a threaded clean-out plug near the bottom. An inlet fixture (1-inch diameter) was located at the center of the east end. The tank construction indicates that it at one time had been used for heavy fuel oil storage, such as a bunker oil or heavy diesel (#6), and may have been later adapted to store a lighter fuel.

Several holes (several inches in diameter) were found along the top of the tank. The remaining body of the tank contained no observable cracks or holes, except that the inlet structure at the east end of the tank was open. Appurtenant piping was not attached to the tanks.

During initial location and removal activities, the wall of the Spillage tank was inadvertently punctured and a small quantity of fuel (several gallons) was released into adjacent soils before the holes were plugged. As the tank was virtually full of fuel, it appears that there had been little, if any, leakage since tank use was discontinued.

## 5.5 Soils Excavation and Ground-Water Removal

#### Tank 1

The petroleum-affected soils immediately adjacent to the tank were removed during field area excavation work, as described above. Standing ground water in the tank excavation, which contained a thin sheen of oily residue, was pumped into a vacuum truck and transported under hazardous waste manifest by H&H Ship Services to their receiving facility in San Francisco.

#### Tank 2

Soils affected by diesel spillage during the removal of Tank 2 were added to the existing stockpile of petroleum-affected soils. Ground water in the open excavation was pumped into a vacuum truck with the ground water from the Tank 1 excavation and transported as described above.

Approximately 500 gallons of ground water were pumped from the two excavations. A copy of the hazardous waste manifest for this water is included in Appendix B.

## 5.6 Excavation Backfilling

Tank excavations were backfilled during grading work being performed simultaneously at the site by Vintage Properties subcontractors.

## 5.7 Sampling Locations and Chemical Analyses

Soil samples were collected in clean brass tubes from the bucket of a backhoe. Sample tubes were labeled, capped with aluminum foil and plastic caps, and sealed with electrical tape. Samples were temporarily stored in a chilled cooler for transportation to the analytical laboratory (Brown and Caldwell Laboratories of Emeryville, California). Samples were transported under strict chain-of-custody protocol.

As required by the AFD on-site representative, two soil samples from each tank excavation were collected. Sampling depths corresponded to the depth of the ground water. Sample locations are shown on Figure 3.

Ground-water samples from the Tank 1 excavation was collected in 40 ml volatile organic analyzer (VOA) containers.

Soil and ground-water samples were analyzed for TPH using EPA Method 8015. The ground-water sample was additionally analyzed for purgeable aromatics using EPA method 602. Analysis results indicate that soils and ground water do not contain petroleum hydrocarbon concentrations above current regulatory guidelines and that petroleum-affected soils have been adequately removed from around the tanks. The ground water did not contain concentrations of purgeable aromatics (BTXE and 1,2-, 1,3- and 1,4-dichlorobenzenes) above the DOHS State action levels.

Analysis data is summarized in the table on Figure 3. Laboratory certificates are included in Appendix A.

#### 6.0 FUEL FINGERPRINTING ANALYSIS

Fuel samples were collected from inside the two tanks for fuel identification (labeled as Tank 1 product, from the 1,500-gallon capacity tank, and Tank 2 product and Tank 2 Sludge, from the 2,400-gallon capacity tank). Additionally, a sample of a very viscous oil (labeled as Soil Product) observed near sampling location 5 (as described in section 2.3) was submitted for analysis. Several soil samples containing petroleum product were also fingerprinted. Farr, Friedman, and Bruya, Inc., a specialty fuel identification laboratory in Seattle, Washington, performed the identifications.

The products in both fuel tanks were identified as a #2 Diesel fuel, although the Tank 1 and Tank 2 products were not identical. The viscous oil was identified as a heavy residual product, such as a Bunker C fuel.

Previous identification of the TPH encountered during initial soil borings in March 1988 (also performed by Farr, Friedman and Bruya, and referenced in their current July 5, 1988 report included in Appendix A) indicated that the product resembled a #6 Diesel, a product heavier than a #2 Diesel but lighter than a Bunker C fuel.

The petroleum hydrocarbon encountered in soils outside the 1,500 gallon capacity tank (Samples Tank1-N1 and PHF27) was identified as a weathered #2 Diesel oil. The petroleum hydrocarbons in two soil samples from other parts of the site (PHF35/36 and PHF45) were identified as a heavy diesel fuel (possibly a #6) and a heavy residual petroleum distillate.

Fuel identification data is included in Appendix A.

Based on these identifications, there appears to be a combination of products distributed at the site. However, apart from the apparent leakage of #2 Diesel from the 1,500-gallon capacity tank into surrounding soils, the source of the other, heavier products is not evident. The construction of the 2,400-gallon capacity tank, as discussed in Section 5.4, does however suggest that heavier fuels had been used at the site at one time.

The available information does not enable us to assess how these fuels were introduced into the subsurface. The product distribution across the site appears to have occurred with ground-water movement, since it coincides with the depth of the ground water. Additionally, subsurface conduits, such as the redwood tunnel and drainage culvert, could have provided transport avenues.

## 7.0 SUMMARY AND CONCLUSIONS

As reported above, Levine Fricke observed the excavation of petroleum-affected soils and the removal of two underground fuel storage tanks. Based on field observations and laboratory data obtained during the work, the following statements can be made.

- Diesel-affected soils across an area of approximately 6,300 square yards and a thickness of about 1 foot were excavated. The diesel-affected soils occurred at about the depth of the ground-water level.
- o The volume of soils removed and stockpiled is about 5,000 cubic yards, and reflects some bulking and over-excavation beyond the in-place volume of diesel-affected soils.
- o Laboratory analysis results of soil samples collected from the excavation boundaries indicate that diesel-affected soils have been adequately removed from the site. Reported

concentrations remaining in the soils are mostly not detectable, and otherwise only one sample contained 60 ppm. This relatively low concentration at a localized sampling point should not require any further action.

- Two underground diesel storage tanks, which have been in the ground for at least 45 years (as estimated from a 1943 Sanborn Map), were removed and disposed of with a hazardous waste manifest. There was evidence of leakage from one of the tanks (1,500-gallon capacity), as indicated by a hole on the tank bottom, the presence of water in the tank, and the product observed in the surrounding soils. The other tank apparently had not leaked, as indicated by tank integrity and the fact that the tank was virtually full of fuel.
- o The fuels inside the tanks, and ground water from the tank excavations were pumped into vacuum trucks and disposed of with hazardous waste manifests.
- O The fuels inside the two tanks were identified as #2 Diesel. Other product encountered in soils at the site was identified as including #6 Diesel and Bunker C fuel.

The source(s) of the fuels encountered in the soil are not distinguishable based on field evidence and laboratory data, except for leakage of #2 Diesel from one of the tanks. It is assumed that the heavier fuels were introduced to the site when previous industrial facilities were active on and in the vicinity of the site. Distribution of the products at that time likely occurred with ground-water movement and transport through subsurface conduits such as the redwood tunnel and drainage culvert. However, over the years the product has degraded and has become relatively immobile in the subsurface. There appears to be little impact of the petroleum products on current ground-water quality.

Characterization results of the stockpiled soils indicated the presence of extractable TPH at concentrations between 85 and 370 ppm. These results indicate that the soils are not classified as a hazardous waste, defined by the Department of Health Services (DOHS) as soils exceeding 1,000 ppm concentration of TPH. However, these concentrations still classify the soils as a designated waste (over 100 ppm). According to this guideline, used by the Regional Water Quality Control Board (RWQCB), the soils do not qualify for disposal at a Class III landfill. Aromatic compounds were generally not detected, except for toluene at very low concentrations of 0.013 and 0.018 ppm.

- o It is anticipated that the RWQCB will require monitoring wells within the excavated area to document post-remediation ground-water quality.
- o Bioremediation of stockpiled diesel-affected soils is presently planned on an adjacent parcel owned by Vintage Properties.

#### LABORATORY ANALYSIS REPORT

LEVINE-FRICKE CONSULTING

1900 POWELL STREET

EMERYVILLE, CA 94611-4567

ATTN: ELIZABETH NIXON

CLIENT PROJECT NO: 1245

**REPORT DATE: 08/12/88** 

DATE SAMPLED: 06/21-24/88 DATE RECEIVED: 06/24/88

DATE ANALYZED: 07/08-11/88

MED-TOX JOB NO: 8806172

ANALYSIS OF: EIGHT SOIL SAMPLES FOR TOTAL PETROLEUM

**HYDROCARBONS** 

METHOD: EPA 8020, 8015 (PURGE & TRAP AND EXTRACTION)

Sample Identification Client Id.	Lab No.	Total Petroleum Hydrocarbons As Diesel (mg/kg)
PHF-25	06A	ND
PHF - 27	A80	1400
PHF-37	10A	ND
PHF-38	11A	ND
PHF-40	13A	ND
PHF-42	15A	ND
PHF-44	17A	ND
PHF-45	18A	60
Detection Limit ND = Not Detected		50

\* Note: TPH fraction found in samples was quantitated as

Diesel, although it consists of predominately heavier

hydrocarbons.

This is a revision of report orginally done 07/13/88.

Michael J. (Jagger, Manager

James K. Farr, Ph.D. Andrew John Friedman James E. Bruya, Ph.D. 3008 B - 16th West Scattle, WA 98119 (206) 285-8282

July 5, 1988

Elizabeth Nixon, Project Leader Levine-Fricke, Inc. 1900 Powell, 12th Floor Emeryville, CA 94608

Dear Ms Nixon:

Enclosed are the results of the analyses of samples submitted on June 28, 1988 from your Alameda Marine Village project.

I have compared these chromatograms with those we ran for samples SB11-2-2 and SB9-1-2 in April of this year. Those soil samples contained a product similar in boiling range to a #6 diesel. The product in the sample labelled "soil product" submitted on June 28 was a material with a substantially higher boiling range. This is indicated by the fact that the abundance maximum for the "soil product" sample was at ca n- $C_{22}$  as opposed to ca n- $C_{17}$  as was found in the previous samples. I'm not sure what to say about this, except that the material previously submitted appeared to be a heavy diesel oil, and that the "soil product" appears to be a heavier material yet.

We appreciate this opportunity to be of service to you on this project. If you have any questions regarding this material, or if you just want to discuss any aspect of your projects, please do not hesitate to contact me.

Sincerely,

Andrew John Friedman, Chemist

### **ENVIRONMENTAL CHEMISTS**

Date of Report: July 5, 1988 Date Submitted: June 28, 1988 Project: Alameda Marine Village

## FINGERPRINT CHARACTERIZATION BY CAPILLARY GAS CHROMATOGRAPHY

Sample #

GC Characterization

Tank 1 Product

The gas chromatographic trace was indicative of a #2 Diesel fuel. This characterization is based upon the even distribution of n-alkanes extending from n-C<sub>10</sub> to n-C<sub>25</sub> (maximum at n-C<sub>17</sub>) and the characteristic abundances of pristane and phytane.

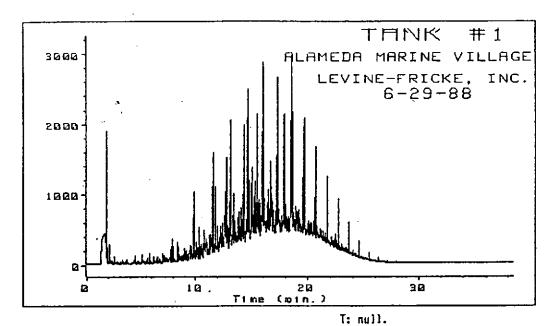

Tank 2 Product

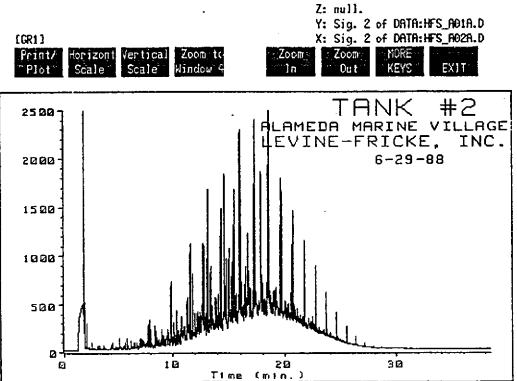

The gas chromatographic trace was indicative of a #2 Diesel fuel. This characterization is based upon the even distribution of n-alkanes extending from n-C<sub>10</sub> to n-C<sub>25</sub> (maximum at n-C<sub>17</sub>) and the characteristic abundances of pristane and phytane. Although quite similar to the product in tank #1, the two products are not identical.

Soil Product

The gas chromatographic trace was indicative of a heavy residual product such as a Bunker C fuel. This characterization is based on the low abundances of the n-alkanes and the abundance maximum of the unresolved chromatographic mixture being quite high (ca n-C<sub>25</sub>). The product does not contain the aromatic predominance seen in gasification wastes or other asphalt production processes, and this supports the hypothesis that it is a heavy residual fuel.

Dear Ms Nixon:

Enclosed are the results of the analyses of samples submitted on July 20, 1988 from Project 1245.

We appreciate this opportunity to be of service to you on this project. If you have any questions regarding this material, or if you just want to discuss any aspect of your projects, please do not hesitate to contact me:

Sincerely,

Andrew John Friedman, Chemist

Date Submitted: July 20, 1988

Project: 1245

## FINGERPRINT CHARACTERIZATION BY CAPILLARY GAS CHROMATOGRAPHY

Sample #

GC Characterization

PHF-27

The gas chromatographic trace was indicative of a weathered diesel fuel with a boiling range from n-C<sub>10</sub> to n-C<sub>22</sub>, indicating it was probably a #2 diesel fuel. The loss of the smooth alkane distribution is indicative of substantial biological degradation.

PHF-45

The gas chromatographic trace showed only a small amount of a late eluting pattern of n-alkanes, indicating the possible presence of a small amount of a heavy residual petroleum distillate.

Dear Ms Nixon:

Enclosed are the results of the analyses of samples submitted on July 27, 1988 from Project 1245.

I am sorry but we don't seem to have been much help in trying to determine the origins of the material found in this sample. As you will see in the results, we found more questions than answers. I would greatly appreciate it if, as the project continues and you get more information, you could let us know what this material turns out to be. We are always looking to add new things to our repertoire.

We appreciate this opportunity to be of service to you on this project. If you have any questions regarding this material, or if you just want to discuss any aspect of your projects, please do not hesitate to contact me.

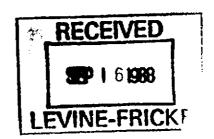

Sincerely,

Andrew John Friedman, Chemist

## FINGERPRINT CHARACTERIZATION BY CAPILLARY GAS CHROMATOGRAPHY

Sample #

PHF-35/36

### GC Characterization

The gas chromatographic trace was indicative of a heavy diesel fuel (possibly a #6) or a mixture of compounds of a nature unknown to us. The chromatogram has a similar pattern to a diesel #6, but not the expected unresolved mass of hydrocarbons. The pattern is also similar to that given by mixtures of PNAs found in coalgasification residues, but a tlc analysis did not find the high PNA level expected in such a case.
