REPORT
SUBSURFACE HYDROCARBON INVESTIGATION
BAY CENTER PROJECT
EMERYVILLE, CALIFORNIA

MARCH 17, 1987

INTRODUCTION

This report presents the results of the additional Phase I work performed by Groundwater Technology, Inc. at the Bay Center Project located in Emeryville, California (See Figure 1, Site Location Map). The additional work was performed in preparation for the installation of a hydrocarbon recovery system, and included the installation of one new monitoring well, the collection and analysis of water samples from both the new and existing wells, and the approximation of the aquifer characteristics.

WORK STEPS

MONITORING WELL INSTALLATION

The purpose of the boring was to explore the site for the presence of subsurface contamination, and to obtain an approximation of the aquifer characteristics. Groundwater Technology located the boring (MW-E) in the assumed down gradient direction from the excavated tank pit, in the vicinity of the proposed recovery well (See Figure 2 - Site Plan).

The boring for the monitoring well was drilled with a truck mounted drill rig using 7.5 inch O.D. (outside diameter) hollow stem augers. The drilling was performed under the direction of

the project geologist who also maintained a continuous log of the materials encountered in accordance with the Unified Soil Classification System. (See Appendix I - Drill Log).

The monitoring well was constructed with two-inch diameter PVC schedule 40 pipe and well screen. The 0.020 inch slotted well screen was installed from the bottom of the boring to 7 feet below ground surface. Blank casing was then installed to the surface. A well pack consisting of #2 Monterey sand was placed in the annulus (the space between the borehole and well casing) from the bottom of the boring to approximately 6 feet below ground surface. The well was completed with a bentonite seal and grouted with cement to the surface where a traffic rated street box was installed to provide access to the well (See Appendix I for Well Construction Details).

SOIL SAMPLING

Soil samples were obtained during drilling using a 2.5 inch O.D. split spoon sampler lined with three, 2 x 6 inch brass sample tubes. The sampler was driven eighteen inches at each sampling point. Samples were collected at 5 foot intervals beginning at 13.5 feet below ground surface to the bottom of the boring. The collected samples were sealed and capped for subsequent delivery to the laboratory for sieve analyses. Each sample was labeled with the boring number, sample designation number, and depth. All samples remained in the possession of the project geologist until delivery to the laboratory.

Bay Center Project
March 17, 1987

Sieve analyses were performed at the Johnson Division laboratory on three of the collected soil samples for grain size determination to be used in the design of the recovery well (See Appendix II - Sieve Analysis).

WATER SAMPLING

Monitoring wells B through E were developed by hand bailing and sampled with an EPA approved Teflon sampler. Access was not available to monitoring well A due to the presence of construction generated soil piles. The groundwater samples were collected in glass vials with Teflon caps in a manner such that no air was trapped inside and then labeled immediately with the job I.D., sample number, date, time and type of analysis requested. The samples were then stored on ice in a thermally insulated cooler until delivery to the laboratory. Analyses for organochlorine pesticides, PCB's, volatile organics and base/neutral acids were conducted by EPA Methods 608, 624 and 625.

AQUIFER TEST

A modified slug test/bail down test was performed on the new monitoring well. In brief, this consisted of measuring the static water level in the well, removing a known volume of water and recording the water level versus time until the static level was reattained. Analysis of the data obtained was conducted

Bay Center Project
March 17, 1987

using two methods; Bower and Rice, (1976)¹, and Cooper, et.al., (1967)² to determine approximate values for the aquifer characteristics near the proposed recovery well.

SITE CONDITIONS

HYDROGEOLOGY

The local groundwater gradient was determined after surveying the elevations at the top of the monitoring well casings and subtracting the measured depth to groundwater levels to obtain water elevations (See Table I). The measurements indicate that the gradient is fairly flat (<1%) under the site, and appears to be flowing to the southwest toward San Francisco Bay. All of the monitoring information obtained from monitoring well B shows a decrease in the groundwater elevation which appears as a groundwater depression.

MW-D	24.90	8.61	16.29
MW-E	25.00	8.24	16.76

AQUIFER CHARACTERISTICS

As previously discussed, two methods were used to approximate the hydrogeologic characteristics of the aquifer underlying the site. The Bower and Rice, (1976), method was developed for use in unconfined aquifers with partially penetrating wells such as the Emeryville site conditions. Cooper et. al., (1967), method was designed for fully penetrating wells in confined aquifers of rather low transmissivity. This last method was used only to verify that the approximate values obtained by Bower and Rice were consistent with aquifers of low transmissivity. The following table presents the results of the aquifer characteristic calculations from both methods performed on the data obtained from the December 30, 1986 bail down test of monitoring well E (See Appendix III - Calculations). The calculated values obtained as a result of the bail down test are typical for silty sands and clays similar to the subsurface materials encountered beneath the site.

	AQUIFER CHARACTERISTICS		
	HYDRAULIC CONDUCTIVITY (gpd/ft ²)	TRANSMISSIVITY (gpd/ft)	PUMPING RATE (gpm)
MW-E Bouwer Method	0.98	38.22	0.81
MW-E Cooper Method	1.20	46.75	1.22

Bay Center Project
March 17, 1987

Five gallons of groundwater was removed from the well which created a drawdown of 1.14 feet. The water level was then measured for the next 7.5 hours until the measurements became constant, although the original static level was not reattained within this time frame.

Because capture zone calculations for silty sands and clays are not representative of actual areas of influence, they were omitted and the radius of influence, where the pumping well draw-down equals 0.25 feet, was assumed to be a more realistic value in determining the zone down gradient which should be affected by pumping and groundwater treatment activity (See Appendix III, Calculations). This approach yielded approximate down gradient capture distances of 60 to 70 feet.

GROUNDWATER CONTAMINATION

The results of laboratory analyses performed on groundwater samples from the site indicate that although hydrocarbon contamination and some acid extractable organics and base/neutral organics are present in the wells sampled, the levels are significantly lower, if detectable, than previously reported in the report prepared by Aqua Science Engineering titled, "Phase II - Extent of Groundwater Contamination Investigation, Bay Center". (See Tables III and IV and Appendix IV - Water Analysis).

CONCLUSIONS & RECOMMENDATIONS

Because the latest groundwater analysis data indicates that the contaminants present are volatile organics, Groundwater Technology believes that groundwater extraction combined with air stripping treatment is the best recovery approach for this site. The latest laboratory analyses indicate that additional treatment for pesticides, PCB's and most acid and base/neutral organic compounds will not be necessary. Therefore, the groundwater extraction system would include a pumping well, PW-1, equipped with a 1/2 hp water table depression pump with Teflon seals and one probe scavenger (See Figure 3, Typical Recovery System). The recovery well would likely be located near monitoring well E

FIGURE 3
CROSS SECTION
TYPICAL RECOVERY SYSTEM

MARTIN COMPANY

NO SCALE

GROUNDWATER
TECHNOLOGY

Bay Center Project
March 17, 1987

and the excavated tank pit. Well construction would consist of 10-inch diameter stainless steel 0.030 slotted well screen and blank casing placed within a 24 inch borehole. The well would be packed in the same manner as the monitoring wells with sand placed in the annulus from the bottom of the boring to 2 feet above the top of the screen and sealed with 1 foot of bentonite and concrete. A traffic rated vault box would be installed such that the recovery well and the associated pump control panels are located below grade.

Groundwater withdrawn from the pumping well would be transported to the treatment compound through a below grade piping system. A water treatment system would be installed to remove the dissolved petroleum hydrocarbons. The following three treatment steps must be evaluated in the preliminary design of the treatment system:

1. Microbiological treatment
2. Inorganic treatment
3. Removal of the dissolved organics

The purpose of and technologies potentially employed in each of these treatment steps are detailed in Appendix V. After obtaining the results of background water quality sampling, Groundwater Technology engineers would perform a thorough evaluation of the results and determine final design specifications for an effective scale prevention system.

Bay Center Project
March 17, 1987

The location of the treatment complex will be determined by the Martin Company, Groundwater Technology, and other involved parties based on technical considerations, environmental concerns, aesthetics, and to facilitate the development of the site.

Air stripping is proposed as the preferred treatment system for removal of the dissolved organics. Air stripping achieves high removal efficiencies and is more cost effective than liquid-phase activated carbon. The Bay Area Air Quality Management District may place limitations of up to 15 pounds per day or 200 ppm total hydrocarbons (THC) on air emissions and may limit other air stream constituents such as benzene. These limitations may require the use of an additional vapor phase carbon or catalytic conversion system for treatment of air emissions.

Because we are anticipating the presence of free floating hydrocarbons on the water table, Groundwater Technology will be installing a double-pump system within the recovery well. One pump will depress the water table, forming a "cone of depression". The second pump will recover any free floating product which collects within the recovery well. Recovered product will be stored on-site in a 630 gallon cylindrical polypropylene tank. The product recovery pump will operate automatically whenever free product is present in the recovery well. It is impossible to predict recovery rates prior to

Bay Center Project
March 17, 1987

operation; therefore, Groundwater Technology will install a tank full sensor which would automatically shut-off the product pump to prevent overfilling. A totalizer would also be installed to quantify recovery rates.

The water table depression pump and the air stripping system will operate continuously. It is anticipated that the recovery well can sustain pumping rates of 1 to 3 gpm. The contaminated groundwater will be treated using a one foot diameter by 27.5 foot tall air stripping tower. Effluent from the treatment system will be discharged into the storm sewer after obtaining a NPDES permit. The system will initially be operated without discharging the effluent while obtaining effluent analyses to verify compliance with permit requirements.

During operation of the treatment system, air emissions will be calculated using the results of laboratory analyses performed on influent and effluent water samples. Based upon the enclosed analytical laboratory data (See Appendix IV) Groundwater Technology anticipates influent concentrations of 13 ppm total volatile organic compounds to the air stripping system. With this defining parameter, worse case mass emissions to the atmosphere are estimated at 0.78 lbs/day total volatile hydrocarbons (mass emission calculations are included as Appendix VI).

Influent and effluent water samples will be obtained bi-weekly for the first month. After the first month, liquid influent will be monitored on a monthly basis until air emissions have stabilized.

Bay Center Project
March 17, 1987

Based upon field inspection, laboratory analyses and preliminary calculations, Groundwater Technology believes one operating recovery well, pumping between 1 and 3 gpm, has the ability to draw the contaminated water from around the old tank pit, capture the water up to 70 feet down gradient and have some influence on groundwater movement as far away as the corner of LaCoste and 64th Street. Therefore, it is Groundwater Technology's opinion that the Martin Company should proceed with the recovery system operating with one pumping well, as presented in the proposal titled, "Bay Center Project Emeryville, California, dated October 1986 and as described within this report.

CLOSURE

Groundwater Technology would like to thank the Martin Company for the opportunity to conduct this subsurface hydrocarbon investigation. Should you have any questions or require additional information with respect to this site, please contact us.

SO MANY CONSIDERATIONS ENTER INTO THE MAKING OF A GOOD WELL THAT, WHILE WE BELIEVE SLOT SIZES FURNISHED OR RECOMMENDED FROM SAND SAMPLES ARE CORRECT WE ASSUME NO RESPONSIBILITY FOR THE SUCCESSFUL OPERATION OF JOHNSON WELL SCREENS.

AQUIFER CHARACTERISTIC CALCULATIONS

BOUWER AND RICE

Aquifer characteristic calculations were performed following the methods outlined in the water resource paper written by Bouwer and Rice, (1976). A semilogarithmic plot of the head loss (y) verses time (t) was prepared for the data obtained. The value of the term $(1/t) \ln y_0/y_t$ is obtained from the best-fitting straight line from the plotted data choosing an arbitrary time and it's equivalent head loss.

The value of $\ln R_e/r_w$ can be evaluated from the electrical resistance analog results and the following equation:

$$\ln R_e/r_w = \left[\frac{1.1}{\ln(H/r_w)} + \frac{A + B \ln [(D-H)/r_w]}{L/r_w} \right]^{-1}$$

where: A and B are dimensionless coefficients that are functions of L/r_w and are obtained from Figure 3 from the Bouwer and Rice paper. If the aquifer thickness, D, is significantly greater than the saturated screen thickness, H, then a value of 6 can be used for $\ln[(D-H)/r_w]$.

The hydraulic conductivity, K, is then determined from:

$$K = \frac{r_c^2 \ln (R_e/r_w)}{2L} \frac{1}{t} \ln y_0/y_t$$

After determining the hydraulic conductivity, the pumping rate (Q) can be calculated to determine the potential discharge which can be expected to be obtained from the recovery well.

$$Q = 2\pi KL \frac{y}{\ln (R_e/r_w)}$$

Aquifer transmissivity can be determined from:

$$T = KH$$

where: H equals the saturated thickness of the well screen interval.

- 1 Bower, H. and Rice, R.C., 1976, "A Slug Test for Determining Hydraulic Conductivity of Unconfined Aquifers with Completely or Partially Penetrating Wells" Water Resources Research, Vol. 12, No. 3 p. 423-428.

Bail/Slug Test Analysis

Method: Bouwer and Rice, 1976

Project: Martin Company

Well No.: MW-E

Date: December 30, 1986

r_w = boring radius

r_c = well casing radius if the water level is above screen
or

r_c = cross sectional area of well that relates Q to dy/dt if
the water level is within perforation section of screen

y = head loss

H = saturated screen thickness

L = perforated screen thickness

D = total aquifer thickness

K = hydraulic conductivity

Q = pumping rate

T = transmissivity

t = time in days

Given:

$$r_w = 3.75 \text{ inch} = 0.3125 \text{ ft.}$$

$$r_c = 1.00 \text{ inch} = 0.083 \text{ ft. (water level above screen interval)}$$

$$r_c = 2.20 \text{ inch} = 0.183 \text{ ft. (water level within perforations)}$$

from

$$r_c = [(r_c)^2 + \eta (r_w^2 - r_c^2)]^{1/2}$$

$$\eta = \text{porosity of sand pack} = 30\%$$

$$H = 39 \text{ ft.}$$

$$L = 40 \text{ ft.}$$

$$D = \infty$$

$$(1/t) \ln Y_0/y_t \quad \text{at } t = 80 \text{ sec } y_t = 0.45 \text{ ft.} \quad = 0.015 \text{ sec.}$$

$$H/r_w = 125$$

$$L/r_w = 128$$

$$A = 5$$

$$B = 83$$

$$\ln[(D-H)/r_w] = 6$$

Then:

$$\ln R_e/r_w = \left[\frac{1.1}{\ln(H/r_w)} + \frac{A + B \ln [(D-H)/r_w]}{L/r_w} \right]^{-1}$$

$$\ln R_e/r_w = \left[\frac{1.1}{\ln(125)} + \frac{5 + 83 \ln [6]}{128} \right]^{-1}$$

$$\ln R_e/r_w = 0.241$$

$$K = \frac{r_c^2 \ln (R_e/r_w)}{2L} \frac{1}{t} \ln y_0/y_t$$

$$K = \frac{(.183 \text{ ft.})^2 (.241)}{2 (40 \text{ ft})} (0.015 \text{ sec})$$

$$K = 1.5 \times 10^{-6} \text{ ft./sec}$$

$$K = 0.131 \text{ ft/day}$$

$$K = 0.980 \text{ gpd/ft}^2$$

$$Q = 2 \pi K L \frac{y}{\ln(R_e/r_w)}$$

$$Q = 2 \pi (0.131 \text{ ft./day})(40 \text{ ft}) \frac{(1.14 \text{ ft})}{(.240)}$$

$$Q = 156.4 \text{ ft}^3/\text{day}$$

$$Q = 0.81 \text{ gpm}$$

$$T = KH$$

$$T = (0.980 \text{ gpd/ft}^2)(39 \text{ ft})$$

$$T = 38.22 \text{ gpd/ft.}$$

Where will s = 0.25 ft.

$$W(u) = \frac{s T}{114.6 Q}$$

$$W(u) = \frac{(0.25)(38.22)}{114.6 (0.81)}$$

$$W(u) = 0.1029$$

$$(u) = 1.5$$

$$r = \left(\frac{(u T t)}{1.87 s} \right)^{1/2}$$

$$r = \left(\frac{(1.5)(38.1)(30)}{1.87 (0.25)} \right)^{1/2}$$

$$r = 60 \text{ ft.}$$

COOPER, BREDEHOEFT AND PAPADOLPULOUS METHOD

Aquifer characteristic calculations were performed following the methods outlined, and using the "type curves" presented in the water resource paper written by Cooper, et.al. (1967). A semilogarithmic plot of the ratio of the measured head to the head after groundwater removal (H/H_0) versus time (t) was prepared for the data obtained. The semilogarithmic plot from well E was superimposed over the "type curve" of a well of finite diameter until a best fit was obtained. The value of t was determined at the match point such that $Tt/r_c^2 = 1.0$. The transmissivity is found by the following formula:

$$T = \frac{1.0r_c^2}{t}$$

The value of storativity can be found from the value of the u-curve generated from the field data and computed using the following formula:

$$S = (r_c^2 u) / r_s^2$$

The coefficient of permeability or hydraulic conductivity can be calculated from:

$$K = T/b$$

After determining the transmissivity, storativity and hydraulic conductivity the pumping rate (Q), can be calculated to determine the potential discharge which can be expected to be

obtained from the recovery well. To determine the pumping rate the "well function of u" $W(u)$ must be known. This can be determined from the following Theis Nonequilibrium Equations and a chart displaying values of $W(u)$ corresponding to values of u .

$$u = \frac{1.87 r^2 s}{Tt}$$

$W(u)$ = corresponding chart value of u

$$Q = \frac{T_s}{114.6 W(u)}$$

REFERENCED CITED

Bail/Slug Test Analysis

Method: Cooper, Bredehoeft and Papadopolous, 1967

Project: Martin Company

Well No.: MW-E

Date: 12/30/86

r = boring radius
r_c = well casing radius
r_s = well screen radius
H_o = water level difference after baildown
H = difference in water levels between t and t_o
b = well screened interval below the water table
s = saturated aquifer thickness minus water column
thickness necessary to operate pump
T = transmissivity
K = hydraulic conductivity
S = storativity
t = time in days
t₁ = time at curve match point

Given:

r = 3.75 inch = 0.3125 ft.
r_c = 1 inch = 0.083 ft.
r_s = 1 inch = 0.083 ft.
b = 39 feet
s = 32 feet
t₁ = 1.6 min.
u = 10⁻¹

Then:

$$T = \frac{(1.0)(r_c)^2}{(t_1)}$$

$$T = \frac{(1.0)(0.083)^2}{(1.6)}$$

$$T = 0.00434 \text{ ft.}^2/\text{min}$$

$$T = 6.25 \text{ ft.}^2/\text{day}$$

$$T = 46.75 \text{ gpd}/\text{ft.}$$

$$K = \frac{(T)}{(b)}$$

$$K = \frac{(46.75)}{(39)}$$

$$K = 1.20 \text{ gpd}/\text{ft.}^2$$

$$S = \frac{(r_c^2 u)}{r_s^2}$$

$$S = \frac{(0.083)^2(10^{-1})}{(0.083)^2}$$

$$S = 10^{-1}$$

$$u = \frac{1.87 r^2 s}{Tt}$$

$$u = \frac{(1.87)(0.3125)^2(.1)}{(46.75)(30)}$$

$$u = 1.3 \times 10^{-5}$$

$$W(u) = 10.6734$$

$$Q = \frac{T s}{114.6 W(u)}$$

$$Q = \frac{(46.75)(32)}{(114.6)(10.6734)}$$

$$Q = 1.22 \text{ gpm}$$

Where will $s = 0.25 \text{ ft.}$

$$W(u) = \frac{s T}{114.6 Q}$$

$$W(u) = \frac{(0.25)(46.75)}{(114.6)(1.22)}$$

$$W(u) = 0.08359$$

$$u = 1.6$$

$$u = \frac{(1.87)(r)^2 s}{Tt}$$

$$r = \left(\frac{u T t}{1.87 s} \right)^{1/2}$$

$$r = \left(\frac{(1.6)(46.75)(30)}{(1.87)(0.25)} \right)^{1/2}$$

$$r = 70 \text{ feet}$$

APPENDIX V
GROUNDWATER TREATMENT SYSTEM

In general, treatment system objectives are to:

1. Accommodate the initial maximum flow rate to the system.
2. Provide system effluent water quality as defined by the Regional Water Quality Control Board or as required by the appropriate municipality.
3. Meet Regional Air Quality Standards for emissions, if applicable.

There are three basic steps in the groundwater treatment process:

1. Inorganic treatment
2. Microbiological treatment
3. Removal of dissolved volatile organics

The purpose of and technologies potentially employed in each of these treatment steps are explained below.

INORGANIC TREATMENT

The potential for inorganic fouling exists in any water treatment process. Inorganic fouling manifests itself in the form of precipitation reaction products; insoluble reaction products of an aqueous chemical reaction. Once water has been taken from its source, where it may have been in a state of equilibrium, it is often exposed to pumping, aeration, and heating, any of which may upset its stability and lead to corrosion or scaling. These insoluble reaction products (scale) form in contacting equipment such as stripping towers, reverse osmosis units and boilers. Ionic species of concern are carbonates (CO_3^{-2}) sulfates (SO_4^{-2}), phosphates (PO_4^{-3}) and hydroxides (OH^-).

As with any prescription or treatment, a thorough system evaluation and diagnosis is a prerequisite. In evaluating equilibrium conditions of an aquatic system for the possibility of scale formation, reaction rates and mechanisms must be considered.

A technique that has found wide spread use, due to its cost effectiveness for scale prevention has been threshold treatment. These chemical dosing systems possess unusual threshold properties which effectively stabilize conditions of supersaturation. This phenomenon results when the inhibitor species (usually a phosphate or phosphonate polymer) is adsorbed on the nuclei from which crystallization would normally proceed. The result is an inactivation of the nuclei and the prevention of precipitation of the scaling constituents.

MICROBIOLOGICAL TREATMENT

In considering aquatic systems, micro-organisms may be placed in three categories: bacteria, fungi and algae. Fungi and bacteria are classified as reducers. Reducers breakdown chemical compounds to more simple species, thereby extracting the energy needed for their growth. Algae are classified as producers because they utilize light energy and store it as chemical energy. In a sense, bacteria and fungi may be looked upon as environmental catalysts, whereas algae are aquatic "solar fuel cells".

THE PROBLEM

Contacting systems whether they be liquid-vapor, liquid-solid or vapor-solid, are utilized for transferring mass, heat and/or momentum between phases, subject to constants of physical and chemical equilibrium. The development, design and implementation of groundwater and waste water treatment systems require mass transfer and separatory equipment; specifically packed towers, filter beds and granular activated carbon beds. Micro-organism growth may occur in contacting and recovery equipment due to the large surface area of micro-organisms through either the makeup water or through air contact. Another factor to be considered is the availability of nutrients and sunlight that promote growth in, and during the contact process.

Chlorine is the most commonly used disinfectant employed for killing bacteria in water. Oxidizing biocides such as chlorine and the hypochlorites will kill organisms present in the system, if the free chlorine comes into direct contact with organisms long enough and at a strong enough level. They also retain their effectiveness because organisms can not adapt to or become resistant to chlorine.

However, oxidizing biocides also react with contaminants and other organics. This increases the amount of chlorine required for biocidal effects. They are not persistent and they decay quickly after the chemical feed stops. Also, they do not penetrate slime masses, they lose their effectiveness as PH increases and chlorinated biocides increase the total dissolved solids (TDS) content of the water. Another disadvantage is the formation of trihalomethanes (THM's), known carcinogens, from the reaction of chlorine with organic compounds.

When micro-organisms are exposed to ultraviolet light, a constant fraction of the number present die in each time increment. The fraction of the initial number of micro-organisms present at a given time is called the survival ratio. The fraction killed is one minus the survival ratio.

For each given micro-organism and UV wave length, the fraction killed depends upon the product of UV light intensity and exposure time. This product is known as the dosage, which is the single most important parameter for rating UV disinfection equipment.

Advantages of ultraviolet treatment include its ability to destroy slime forming bacteria and pathogens at relatively low dosages, its ability to leave treated water unchanged with respect to color, PH, temperature, conductance or scaling tendency. Also there are no adverse health effects for operators. The major drawback to UV treatment is the limited quantity of influent treated per pass.

Ozone is sometimes used as a disinfectant in place of chlorine. Basically, air is filtered, cooled, dried, and pressurized, then subjected to an electrical discharge of approximately 20,000 volts. The ozone produced is then pumped into a contact chamber where water contacts the ozone for 10-15 minutes. The recent concern over possible production of toxic organochlorine compounds, such as THM's, by water chlorination processes has increased interest in ionization.

VOLATILE ORGANIC COMPOUND REMOVAL

Either of two technologies are commonly employed in the removal of organic compounds from groundwater: air stripping or liquid phase granular activated carbon.

AIR STRIPPING

Air stripping is a technique for the removal of volatile compounds which are either dispersed or dissolved in water. The water is fed over a large surface area, maximizing the surface contact between water and air, thus allowing the contaminants to be stripped from the water.

The Groundwater Technology (GT) Air Stripping system quickly and economically removes volatile organic pollutants from water. Applications include groundwater and waste water contaminated by petroleum hydrocarbons and chlorinated organics.

The Groundwater Technology design, shown in Figure A-1 utilizes the packed tower method of air stripping. The air stripping system consists of a vertical column containing a unique packing material, air blower, motor and controls. Standard GT towers feature the highest quality contact molded FRP (Fiberglass Reinforced Plastic) construction available. All standard towers have a minimum of 1/4" wall thickness and a minimum wind load design rating of 100 mph. Where local codes exceed 100 mph, or tower extensions are used, guy wire assemblies are required. Flow rates up to 1000 gpm can be handled by a single unit. Larger flows and/or higher concentrations can be handled with units in series or parallel configurations.

FIGURE A-1
CROSS SECTION
TYPICAL RECOVERY SYSTEM

Inherent features of all standard GT Air Strippers include:

- FRP tower shell
- Polypropylene Tripack packing
- Packing support
- Explosion proof blower motor
- Non-sparking aluminum blower wheel
- Blower inlet guard
- Air flow regulator
- Blower flexible duct
- Explosion proof On/Off switch
- 12' cord with ENP plug
- Mist eliminator with safety hold downs
- Removable sight tube assembly
- Top accessory flange
- Full cone spray nozzle (Orifice type)
- Integral sump
- Lifting lugs
- Concrete anchor bolts (tower and blower)
- Sch. 80 PVC influent pipe with sample port
- Guy wire and turnbuckle assemblies

Standard Groundwater Technology, Inc. Air Stripping systems will provide removal efficiencies in excess of 99 percent for the following compounds:

Benzene	Ethylbenzene	1, 2 dichloroethylene
Toluene	Trichloroethylene	1, 1, 1 trichloroethane
Xylene	1, 1 dichloroethylene	Tetrachloroethylene
		Napthelene

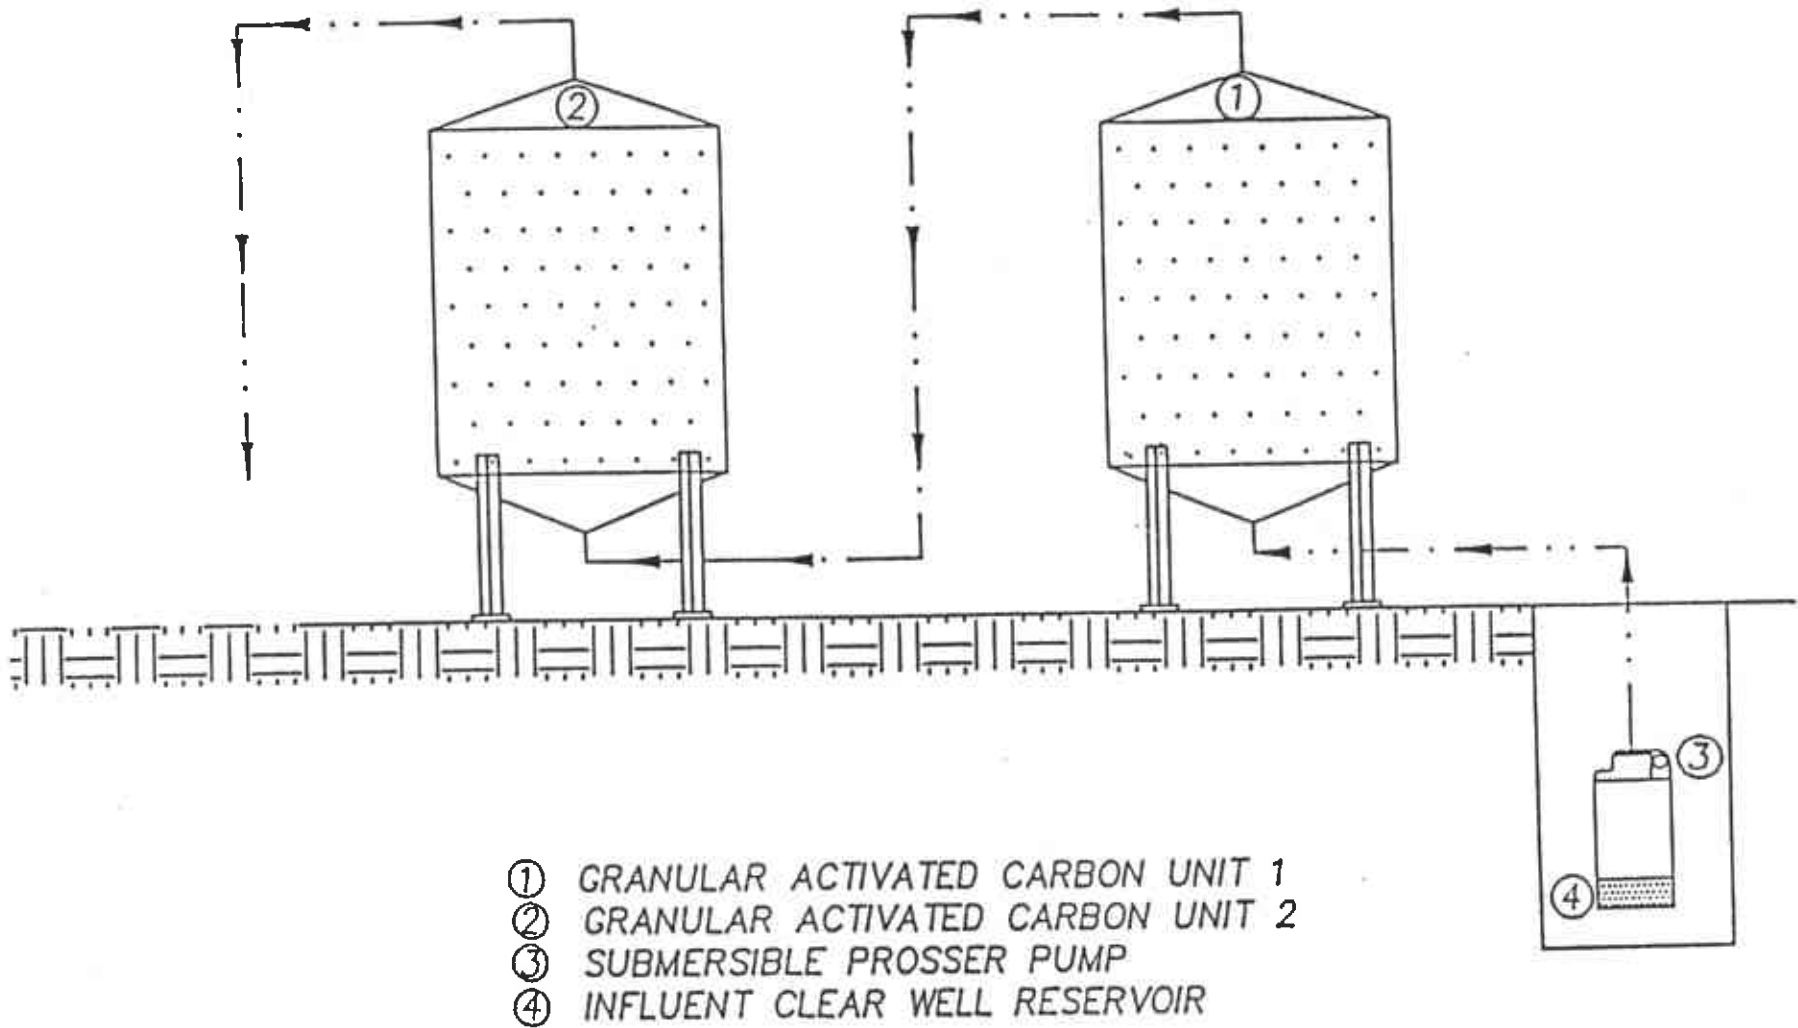

Removal efficiencies for phenols will be approximately 30 percent. If treatment objectives require higher removal efficiencies, several options are viable: an air stripping system with recycle capabilities, air stripping tower with height extensions or substituted high performance packing. Groundwater Technology has been designing and operating air stripping towers for over 6 years. There are currently over 200 installations in operation for flows ranging from 1 to 1000 gpm. Installations have been designed to accommodate both municipal drinking water and industrial waste water standards.

GRANULAR ACTIVATED CARBON

Activated carbon adsorbs a great variety of dissolved organic materials including many which are non-biodegradable. Adsorption is facilitated by the large surface area on the carbon granules which are attributable to its highly porous structure. Biological degradation occurring on the granules complements the adsorption process in removing dissolved organic material. Carbon, in certain configurations, also functions as a filter. The greatest cost within the carbon treatment process is the cost of the carbon itself. Thermal regeneration of the spent carbon makes the process economically feasible; the cost of the regenerating equipment, however, represents only a small fraction of the total capital equipment costs.

FIGURE A-2

GRANULATED ACTIVATED CARBON UNITS UPFLOW IN SERIES

The most important design parameter to consider for adsorption vessels is contact time. Hydraulic loading, within the ranges normally used, has little effect on adsorption. The process configurations of the system includes downflow under pump pressure, with fixed beds, and single (parallel) arrangement.

**APPENDIX VI
MARTIN COMPANY
AIR STRIPPING SYSTEM**

Worst Case Mass Balance Analysis

Operating Parameters:

Liquid Loading - 5 gpm (max)

Vapor Loading - 50 scfm

Volatile Priority Pollutant

Total Concentration - 13.0 ppm

Assume 100% Transfer of Contaminants to Vapor

Phase from the Liquid Phase

Assume Vapor Influent has no Contamination Characteristics

Mass Balance Equation

$$(L_{in})(X_{in}) + (V_{in})(Y_{in}) = (L_{out})(X_{out}) + (V_{out})(Y_{out})$$

Where, L = Liquid Loading

X = Contaminant Concentration, Liquid Phase

V = Vapor Loading

Y = Contaminant Concentration, Vapor Phase

and $Y_{in} = X_{out} = 0$

Simplifying, $(L_{in})(X_{in}) = (V_{out})(Y_{out})$

or

$$(V_{out})(Y_{out}) =$$

$$\left(\frac{5 \text{ gal}}{\text{min.}}\right) \left(\frac{13.0 \text{ mg}}{1}\right) \left(\frac{3.785 \text{ l}}{\text{gal.}}\right) \left(\frac{\text{g}}{1000\text{mg}}\right) \left(\frac{\text{lb}}{453.6\text{g}}\right) \left(\frac{60\text{min}}{\text{hr}}\right) \left(\frac{24\text{hr}}{\text{day}}\right) = 0.78 \text{ lbs/day}$$

Concentration of hydrocarbon in discharge, Y_{out} :

$$Y_{out} = \frac{(L_{in})(X_{in})}{V_{out}} = \frac{(5 \text{ gpm})(13.0 \text{ ppm})}{(50 \text{ cfm})(7.48 \frac{\text{gal}}{\text{ft}^3})}$$

$$Y_{out} = 0.174 \text{ ppm}$$
