Re: **Site Summary Conduit Study and Groundwater Monitoring Report**
2345 International Boulevard (formerly E. 14th Street)
Oakland, California
Fuel Leak Case No. RO0000327

Dear Mr. Gholami:

The *Site Summary, Conduit Study and Monitoring Report* (Report) was mailed prior to final review. Please disregard the report sent yesterday, as the Figures were omitted. Enclosed is the Report and accept my sincere apologies for any inconvenience. Cambria looks forward to working with you on this project. If you have any questions or comments, please contact me at (510) 420-3307.

Sincerely,
Cambria Environmental Technology, Inc.

1.0 INTRODUCTION

Cambria Environmental Technology, Inc. (Cambria) is pleased to submit this *Site Summary, Conduit Study and Monitoring Report* (Report) for the above-referenced site on behalf of Mr. Stanley Wong. As requested by the Alameda County Health Care Services Agency (ACHCSA) on September 9, 2002, this report summarizes historical site activities and subsurface conditions, and presents our conclusions and recommendations for the site. This report also describes recent activities conducted by Cambria to facilitate evaluation of the site conditions. The recent activities conducted by Cambria include preparation of geologic cross-sections, a conduit study, groundwater monitoring, and free product removal. As verbally requested by new regulatory case worker Amir Gholami, this report discusses hydrocarbon trends, plume stability, methyl tert-butyl ether, and chlorinated hydrocarbons, and includes a risk evaluation. Mr. Gholami requested comparison of contaminant concentrations to risk-based screening levels (RBSLs) established by the San Francisco Bay Regional Water Quality Control Board (RWQCB).

2.0 SITE BACKGROUND

Site background information is presented below. Boring logs, analytical results and additional information from previous investigations is presented in Appendix A.

2.1 Site Use, Location and Description

The site located is located in a commercial/residential area at the southwest corner of the intersection of International Boulevard (formerly East 14th Street) and Miller Avenue in Oakland, California (Figure 1). The site is at an elevation of approximately 23 feet above mean sea level, based on City of Oakland datum. The site is currently operated by Credit World Auto Sales, a

used car dealership. One building occupies the site, and the building is used as an office and automotive service bay. The remainder of the site is a paved parking area (Figure 2).

In August 1988, SCS removed four underground storage tanks (USTs) along with two dispenser islands and associated piping from the site (Figure 2). Soil samples from the fuel tank showed concentration of total petroleum hydrocarbons as gasoline (TPHg) and benzene. Soil samples from the used oil excavation area showed impact of total petroleum hydrocarbons as diesel (TPHd) and total oil and gas (TOG).

2.2 Site Investigation

Several phases of soil and groundwater assessments have been conducted at the site since 1988. Soil and groundwater analytical results from these investigations is summarized in Tables 2 and 3, respectively.

November 1988: California Environmental Consultants (CEC) advanced three soil borings to assess the extent hydrocarbon impact in the soil and groundwater in the vicinity of the former UST locations. Borings B-1 and B-2 were advanced adjacent to the former fuel USTs. TPHg and benzene, toluene ethylbenzene, and xylenes (BTEX) were detected in the soil and groundwater samples from both borings. Boring B-3, located near the former used oil UST location, showed concentrations of TOG and BTEX in soil and groundwater samples.

May to August 1991: Earth Systems Environmental advanced five onsite borings (TH-1 through TH-5) and installed three groundwater monitoring wells (MW-1 through MW-3) at the site to further delineate the onsite hydrocarbon impact. Borings B-1 and B-2 were advanced adjacent to the former fuel USTs. TPHg and BTEX were detected in the soil and groundwater. Soil and groundwater samples from boring B-3, located near the former used oil UST location, showed concentrations of TOG and BTEX. Groundwater was encountered 19 feet below grade surface (bgs) during this assessment.

July 1993: Tank Protect Engineering (Tank Protect) installed two monitoring wells (TMW-4 and TMW-5) at the site. No petroleum hydrocarbons were detected in soil samples from borings for wells TMW-4 and TMW-5. Separate-phase hydrocarbons (SPH) were observed in wells MW-1, MW-2 and TMW-5 and was removed by hand bailing. Groundwater flow direction beneath the

site ranged from north-northeast to west-southwest with an average gradient of 0.029 feet/feet during this assessment. Tank Protect concluded that confined and unconfined groundwater is present beneath the site, and that wells MW-2 and MW-3 monitor an upper, unconfined water bearing zone while MW-1, TMW-4, and TMW-5 monitor both the upper unconfined zone and a lower, confined water bearing zone. Tank Protect concluded that sands logged in well MW-2 are characteristic of a buried stream channel, trending north-south beneath and across the site.

April 1997 to May 1997: Tank Protect advanced five borings (SB-1 through SB-5) to assess the offsite hydrocarbon impact. TPHg was detected in soil and water samples from boring SB-5 and benzene was detected in boring SB-2. Benzene and methyl tert-butyl ether (MTBE) were detected in groundwater from boring SB-5. No petroleum hydrocarbons or MTBE were detected in soil and groundwater samples from borings SB-1, SB-3, and SB-4. Tank Protect concluded that northern and southern extent of the hydrocarbon plume has been defined.

May 2001: Sequoia Environmental (Sequoia) advanced seven onsite borings (SB-1 through SB-7), converting boring SB-7 into monitoring well MW-6. No MTBE was detected in all soil samples. SPH was detected in wells MW-1, MW-2, MW-3 and TMW-5, and 4.5 gallons of SPH was removed by hand bailing from the monitoring wells. MTBE was not detected in all groundwater samples Sequoia reports groundwater flow to the west-southwest during this assessment.

Groundwater Monitoring: Groundwater monitoring of site wells was conducted regularly between August 1991 and December 1999, and was conducted once in 2001 and once again in 2002. Groundwater analytical data and groundwater elevation data is summarized in Table 3. Results of the groundwater monitoring are described later in this report.

2.3 Site Remediation

In August 1988, SCS removed four USTs, two dispensers and associated piping from the site (Figure 2). Several remedial activities have been conducted since UST removal.

2.3.1 Soil Excavation

December 1994 through October 1996: Tank Protect conducted multiple phases of soil excavation and verification sampling at the site. As shown on Figure 2, the excavation was conducted around the UST area in the center of the site, and the depth of the excavation ranged

from 12 feet to 19 feet bgs. A total of 1,550 cubic yards (cy) of soil was excavated. Approximately 1,019 cy of the excavated soil was stockpiled on site, remediated via aeration and hydrogen peroxide treatment, and placed back into the excavation cavity with the approval of the ACHCSA. Approximately 531 cy of soil was removed from the site and disposed of at a licensed facility. The final verification samples detected a TPHg maximum concentration of 110 milligrams per kilogram (mg/kg) in sidewall samples, and 66 mg/kg in excavation bottom samples. Additional information on excavation activities and confirmation sampling results is presented in Appendix A.

2.3.2 SPH Removal

Due to the presence of SPH in site wells, Tank Protect installed a free product recovery system and bailed site wells during groundwater monitoring events. Groundwater monitoring and sampling results and SPH thickness information is presented in Table 3.

The free product removal system first consisted of a selective oil skimmer, down-well mounted bladder product pump, and two product storage drums. Tank Protect reported that trace quantities of free product were removed during between July 27 and August 18, 1995. To enhance free product recovery, Tank Protect installed a continuously operating free product recovery system in August 1997. Tank Protect reported removing 3 to 5 gallons of SPH between August 20, 1997 and January 14, 1998. SPH removal by manual bailing by Cambria is described below and summarized in Table 5.

2.3.3 Bio-Remediation System

A bio-remediation system was installed and operated at the site by Sequoia between March 2002 and July 2002. According to Sequoia, this system pumped water from four wells (MW-1, MW-2, MW-3 and TMW-5) into four "bioreactor" tanks containing microbes, nutrients, and hydrogen peroxide. The treated, microbe-rich water was then injected into the subsurface through an infiltration well (MW-1). Monthly project updates submitted by Sequoia do not provide detailed information about system layout, startup, or operation. Between March 2002 and July 2002, four bio-treatment events were reported where treated, microbe-rich water was injected into well MW-1. The system was shut down and removed in July 2002. Groundwater samples collected by Sequoia on June 20, 2002 after the initiation of bio-remediation activities were generally

consistent with historical groundwater hydrocarbon concentration trends. Insufficient data is available to assess the effectiveness of the bio-remediation system.

2.3.4 Vacuum Truck Operations

Vacuum truck operations were conducted by Sequoia on July 20, 2002 as an interim remedial measure. Vacuum truck operations were performed to remove the SPH found in wells MW-2, MW-3 and TMW-5. Details are not available describing the length of vacuum truck operations or amount of SPH and groundwater recovered.

3.0 RECENT ACTIVITIES

Cambria prepared geologic cross-sections, conducted a conduit study, monitored site groundwater wells, and bailed SPH from site wells. These activities were required by ACHCSA and are described below.

3.1 Geologic Cross Sections

To illustrate the site's stratigraphic and hydrogeologic characteristics, Cambria constructed geologic cross sections A-A' and B-B' from boring logs (see Figures 3 and 4). The geologic cross sections illustrate that the stratigraphy consists primarily of low to moderately permeable clays and silts with interbedded higher permeability sand and gravel layers to the total depth explored of 36 feet bgs. Two water-bearing units were encountered, and confined and unconfined conditions may be present at the site. Soil analytical results and historic high and low groundwater depths are shown on the cross sections. The site geology and hydrogeology are described further in Section 4.

3.2 Conduit Study

Cambria performed a conduit study to evaluate the potential for subsurface utility conduits to serve as preferential pathways for hydrocarbon migration. To obtain information regarding buried utilities in the site vicinity, Cambria contacted the City of Oakland, Pacific Bell, Pacific Gas & Electric (PG&E), and East Bay Municipal Utilities District (EBMUD). The location, diameter and approximate depth of subsurface conduits beneath and adjacent the site are shown on Figure 5. A

subsurface utility map from the City of Oakland Department of Engineering is included in Appendix B. Based on the City of Oakland map and telephone conversations with Pacific Bell, PG&E and EBMUD, the depth to nearby utilities ranges from approximately 3 to 18 feet bgs. A telephone line is located at approximately 3.5 feet bgs along International Blvd. A sanitary sewer crosses the site (presumably shallower than 5 feet bgs) and enters a 10-inch diameter sanitary sewer beneath the middle of International Boulevard, which is located at approximately 8 to 9 feet bgs (approximate 15 feet flow line elevation). A water line crosses the site (presumably shallower than 5 feet bgs) and enters a 36-inch diameter water main near the other side of International Blvd located at 5 feet bgs. A 24-inch diameter storm drain, also on the other side of International Blvd, is located approximately 3 feet bgs (top of conduit) to 5 feet bgs (bottom of conduit; approximate 18 feet flow line elevation). A sanitary sewer (presumably 6- or 8-inch diameter) is located near the other side of Miller Avenue at approximately 8 to 9 feet bgs (approximate 14 feet flow line elevation). A 75-inch diameter storm drain is located beneath Miller Avenue at approximately 10 to 16 feet bgs, with an approximate 7 feet flow line elevation as it passes the site. Overhead electrical service runs along Miller Avenue.

To compare sewer and utility depths to groundwater depth, Cambria reviewed existing surveying information. Because surveying datum information was not provided in reviewed reports, Cambria contacted the Renner Survey Company of Burlingame, California, who researched old records and determined that the site wells were surveyed to the City of Oakland bench mark datum (See Appendix C).

As described below, site groundwater has historically fluctuated primarily between approximately 9 and 17 feet bgs, and has occasionally risen to approximately 6 feet bgs at some locations. This information suggests that onsite utility conduits and the shallow offsite storm drain beneath International Boulevard, which are shallower than 6 feet bgs, have not historically intersected site groundwater. The two offsite sanitary sewer conduits, located at approximately 8 to 9 feet bgs, do not likely intersect groundwater during its typical fluctuation between 9 to 17 feet bgs, but likely do intersect groundwater during the occasional groundwater rise to approximately 6 feet bgs. Although groundwater could occasionally intersect these sanitary sewer conduits, the prevalent clay in the shallow site subsurface would limit the potential for hydrocarbons to migrate to nearby conduits. Furthermore, groundwater analytical results from offsite borings SB-1, SB-3 and SB-4, located between the site and the sanitary sewers, suggests hydrocarbons have not migrated offsite

toward the sanitary sewers. As described below, no hydrocarbons were detected in soil or groundwater from these borings.

Our primary concern is the 75-inch storm drain beneath Miller Avenue located approximately 60 feet from site well SB-7/MW-6, which had SPH detected (0.04 feet) for the first time during monitoring in December 2002. This 75-inch diameter storm drain, located at approximately 16 feet bgs, apparently intersects groundwater almost year round and could be located within the upper sandy water-bearing unit. However, groundwater analytical results from offsite boring SB-1 (installed in 1997 and located between the site and storm drain) suggest that hydrocarbons have not migrated offsite toward the offsite storm drain (no hydrocarbons were detected in soil or groundwater from boring SB-1).

3.3 Groundwater Monitoring

Cambria conducted gauging and monitoring of site wells on October 21, 2002 and December 27, 2002. During the October 2002 gauging event, groundwater monitoring wells MW-1, MW-3 and MW-6 were not accessible. SPH thickness was observed in wells MW-2 and TMW-5 at 0.24 feet and 0.10 feet, respectively. SPH was not observed in well TMW-4. Depth to groundwater in site wells ranged from 13.6 to 16.98 feet bgs. During the December 27, 2002 monitoring event, SPH was observed in all site wells and groundwater sample collection was not performed due to the presence of SPH. Groundwater monitoring data is summarized on Table 3. A groundwater elevation contour map for December 27, 2002 is presented as Figure 6.

To more accurately estimate the groundwater flow direction at the site, Cambria has estimated the top of casing elevation for wells MW-3 and TMW-4. Site records indicate that other site wells were surveyed to the Oakland datum in June 2001, while wells MW-3 and TMW-4 were not resurveyed at that time. The resurveying in June 2001 by the Renner Survey Company effectively lowered the groundwater elevation of the other site wells (MW-1, MW-2, and TMW-5) by an average of 2.80 feet. Cambria assumes that the wells were previously surveyed to NGVD 29 datum, which is approximately 3 feet higher than the City of Oakland datum. To estimate the top of casing (TOC) elevation for wells MW-3 and TMW-4 with respect to City of Oakland datum, Cambria subtracted 3 feet from the prior TOC elevation from August 1993. Figure 6 and Table 3 present the revised groundwater elevation based on the Oakland datum.

3.4 SPH Removal Activities

During the December 2002 monitoring event, SPH was observed in all site wells. Cambria technicians removed approximately 13.5 liters (21.78 pounds) of SPH from site wells by hand bailing on December 27, 2002. To estimate prior SPH removal by hand bailing and/or well purging by Tank Protect, Cambria multiplied the tabulated SPH thickness (feet) by the well casing area (i. e., 2-inch diameter casing = 0.60 liters per foot) for each purging/bailing event. Cambria estimates that approximately 69.6 pounds of SPH were bailed and/or purged by others. In addition, Tank Protect reported that a continuous free product recovery system removed approximately 3 to 5 gallons (18.3 to 30.5 pounds) between August 1997 and January 1998. As summarized on Table 5, Cambria estimates that 121.88 pounds of petroleum hydrocarbons have been removed from site wells to date.

4.0 SUBSURFACE CONDITIONS

The site geology, hydrogeology, chemicals of concern (COC), and hydrocarbon distribution in soil and groundwater are described below.

4.1 Geology

The site is located within the Coast Range geomorphic province of California. In general, the Coast Range province consists of Jurassic eugeosynclinal basement rocks and Cretaceous and Cenozoic sedimentary and volcanic rocks that have been faulted and folded with a northwest-southeast trend. The site lies within the Bay Plains Basin. Sediments beneath the site consist of coalescing alluvial deposits from the Diablo Range to the east known as the San Leandro Cone. According to the USGS Professional paper 943, the site is located on quaternary age alluvial deposits consisting of medium-grained, unconsolidated moderately sorted permeable fine sand, silt, and clayey silt with thin beds of coarse sand.

The site geology consists primarily of low to moderately permeability clays and silts with interbedded higher permeability sand and gravel layers to the total depth explored of 36 feet bgs. Aggregate base material (fill) under site asphalt at approximately one foot bgs is underlain by dry gray to black or brown clay ranging to total depths of 7½ to 12 feet bgs, with damp gray to green clay to ranging from approximately 17 to 23 feet bgs. This shallow clay is underlain by a

discontinuous water-bearing unit from approximately 17 to 27 feet bgs, which consists of silty to clayey sand grading to brown clayey sand. The silty/clayey sand unit is shallowest near wells MW-2 and SB-7/MW-6. This water-bearing unit is underlain by gravelly clay to a depth of 32½ feet bgs. A deeper relatively permeable sand and gravel layer is present in boring for wells MW-1 and TMW-4 at depths of 31.5 to 35 feet bgs and 30.5 to 32.5 feet, respectively. It cannot be determined if the lower and upper higher permeability sand layers shown in the geologic cross sections are interconnected or separated by the lower permeability clay layers. Geologic cross-sections are shown on Figures 3 and 4. The upper and lower sand units may be discontinuous, and may be confined or unconfined.

The boring logs presented in Appendix A illustrate that wells MW-1 and MW-3 appear to be screened across two water-bearing units. Well TMW-4, screened from 14 to 34 feet bgs, may also be screened across the two water-bearing units; the well screens the lower water-bearing unit at 30 to 32.5 feet bgs and may encounter thin sand stringer units at approximately 15 feet bgs (Figure 4). Similarly, well MW-2 is screened from 15 to 35 feet bgs, and may encounter thin sand stringer units near the lower water-bearing unit at approximately 32 to 36 feet bgs (Figure 3). Based on historic high and low water levels shown on Figures 3 and 4, all site well screens are often fully submerged by site groundwater.

4.2 Hydrogeology

Major groundwater bearing materials beneath the Bay Plain Basin occur at depths ranging from 50 feet to more than 1,000 feet bgs. Groundwater from these aquifers is presently used largely for irrigation and industrial purposes. Regionally, groundwater flow is generally to from the Diablo Range toward San Francisco Bay. The nearest surface water body to the site is Brooklyn Basin Tidal Canal located ½ mile to the west.

Since 1991, the depth to groundwater beneath the site has ranged from approximately 6.5 to 17 feet bgs. However, the groundwater depth has typically fluctuated between approximately 10 to 15 feet bgs. The historical high and low groundwater depths are shown on Figures 3 and 4. Historically, the groundwater flow direction has varied significantly, generally flowing either northwestward or radially outward from the center of the site. Cambria and previous site consultants have inferred a radial direction of groundwater flow based on groundwater elevation data from site wells dating back to August 1993. A radial groundwater flow direction could be

explained by water mounding within the UST cavity (from August 1993 to September 1994) or within the UST excavation (after December 1994 when excavation commenced). It is also possible that infiltrating rainwater enters the former UST excavation area through the asphalt cap or via the onsite water and sanitary sewer conduits presumably located in the unsaturated zone. The radial groundwater flow direction could also be explained by the apparent screening of some site wells across two water-bearing units. The well screen intervals (particularly well MW-1) could also contribute to groundwater mounding beneath the site since the lower water-bearing unit may be confined. However, as described in Section 4.1, the actual groundwater flow direction may be different if based on wells with appropriate screening. Wells are screened for up to 20 feet in length, are screened across two water-bearing units, and are often fully submerged by site groundwater. The well screen intervals do not allow proper evaluation of SPH thickness in the subsurface. Well completion data is summarized on Table 4. The estimated groundwater flow direction from past monitoring events is summarized on Table 1.

4.3 Hydrocarbon Distribution

The COCs at this site are petroleum hydrocarbons as described below. The extent of hydrocarbons in the site subsurface has been assessed by several investigations since 1988. One investigation in 1997 evaluated the offsite extent of hydrocarbons using soil borings. Described below are the COCs and the distribution of hydrocarbons in soil and groundwater.

4.3.1 Chemicals Of Concern

During site investigation activities, only petroleum hydrocarbons and MTBE have been detected in analyzed soil and groundwater. The detected petroleum hydrocarbons are predominately in the gasoline, oil and grease ranges. Oil and grease has been detected primarily near the former used oil UST.

MTBE has been detected in groundwater from one boring grab sample [12 micrograms per liter (µg/L)] and sporadically in select wells by Environmental Protection Agency (EPA) Method 8020. MTBE detection have *not* been confirmed by EPA Method 8260 analysis. No MTBE was detected in site soil. This information suggests that MTBE may not be a COC at this site, and that groundwater analysis by EPA Method 8260 is merited for any detected MTBE by EPA Method 8020.

During removal of the former fuel USTs and the used oil UST (and during an investigation in 1988), select soil and groundwater samples were analyzed for volatile organic compounds (VOCs) by EPA Method 8260 and for halogenated VOCs (HVOCs) by EPA Method 8010. No HVOCs were detected in analyzed samples. Only BTEX compounds detected in samples analyzed for VOCs by EPA Method 8260. MTBE, VOC and HVOC data is presented in Tables 2 and 3. For purposes of the hydrocarbon distribution presented below, petroleum hydrocarbons are considered the COCs for the site.

4.3.2 Soil

Petroleum hydrocarbons were detected in 21 of the 25 borings with analyzed soil samples. Soil analytical results are summarized in Table 2. The extent of TPHg and benzene in soil is shown on Figures 8 and 9, respectively. The vertical extent of TPHg is shown on geologic cross-sections on Figures 3 and 4.

Soil analytical results indicate that petroleum hydrocarbons are primarily located in the capillary fringe and saturated zone at depths ranging from approximately 10 to 25 feet bgs. Shallower unsaturated soil has presumably been remediated by site excavation activities. Limited shallow soil data is available, and the maximum TPHg concentration detected in shallow (<10 feet bgs) was 2.4 mg/kg at 5.5 feet bgs in TMW-5, which was overexcavated around and adjacent the former USTs.

TPHg concentrations in soil are highest north and northwest of former UST excavation area (see Figure 8). The maximum detected TPHg concentrations in subsurface ($\leq$ 10 feet bgs) soil are 4,320 mg/kg TPHg in MW-2 at 10 feet bgs, 1,800 mg/kg in SB-3 at 15 feet bgs, and 450 mg/kg in TH-4 at 19.5 feet bgs. Benzene concentrations in soil are also highest north and northwest of the former UST area, although elevated benzene concentrations are also detected southwest of the former USTs. The maximum benzene concentration detected was 61 mg/kg at 15 feet bgs in B-5, but this sample location from the 1988 UST removal may have been overexcavated. The maximum TOG concentration detected was 1,600 mg/kg in TH-4 at 19.5 feet bgs. This sample was near the former used oil UST location in the northwestern portion of the site.

The lateral extent of hydrocarbons in soil appears to be adequately defined by onsite and offsite borings in all directions, except for benzene in the west and southwest directions. No BTEX

compounds were detected by the four offsite borings (SB-1, SB-3, SB-4, and SB-5) installed in 1997. TPHg was detected in only one of the four offsite borings, at a concentration of 91 mg/kg (SB-5). However, the three offsite borings with no TPHg or BTEX detected were apparently sampled in the saturated zone, at depths of approximately 22 and 27 feet bgs. The one boring sampled near the presumed capillary fringe (SB-5 sampled at 11.5 to 12 feet bgs) had the TPHg detection of 91/ mg/kg. While *soil* sampling may not have adequately characterized capillary fringe soil, *groundwater* analytical results from these four offsite borings suggests that petroleum hydrocarbons have only migrated offsite in the northwest direction (near SB-5). No hydrocarbons were detected in grab groundwater north or south of the site, based on results from SB-1, SB-3 and SB-4 described below.

4.3.3 Groundwater

Groundwater monitoring data and analytical results indicate that SPH is present across the site in all monitoring wells, the SPH plume is not stable, elevated benzene is present onsite, and the hydrocarbon extent is not fully characterized. Groundwater analytical results and monitoring data are summarized in Table 3. The current and historic maximum SPH thickness observed in the site wells is presented in Figure 7. The historical extent of benzene concentration in groundwater is shown on Figure 10.

Cambria observed SPH in all site wells during the most recent monitoring event on December 27, 2002. As shown on Figure 7, the SPH thickness on this date ranged from 0.04 feet (MW-6) to 0.43 feet (MW-2). Most importantly, SPH was detected for the first time in wells TMW-4 and MW-6 during this monitoring event. The maximum SPH thickness reported is site wells has been 7.44 feet in MW-2 (March 1995), 4.36 feet in well MW-1 (June 2001), 0.46 feet in MW-3 (March 1995), and 0.10 feet in TMW-5 (December 2002) (see Figure 7). This indicates that the greatest SPH thickness has been observed north of the former USTs (MW-2) and west-southwest of the former USTs (MW-1 and MW-3). In general, SPH thickness increases when the groundwater elevation lowers, as especially observed in wells MW-1 and MW-3. The SPH appears to be primarily located in the upper sand unit, and is likely present in historic smear zone comprised of clayey soil and possibly thin interbedded sand units. In well MW-2, the SPH thickness is typically highest when the groundwater elevation rises, possibly due to the rising water table entering the upper sand unit where elevated TPHg was detected in soil and SPH is likely present. The submerged well screen is likely effecting the SPH thickness observed in well MW-2. The detection of SPH for the first time in perimeter site wells TMW-4 and MW-6 could be

explained by SPH migration caused by groundwater mounding and the inferred radial groundwater flow direction. The SPH detection could also be explained by historic high groundwater elevation for wells TMW-4 and MW-6 during the recent monitoring.

Groundwater analytical results suggest that dissolved hydrocarbons are present across most of the site, with the highest concentrations near the former UST area. The historical benzene concentrations detected in site groundwater are shown on Figure 9. The highest benzene concentrations (>10,000 µg/L) have been detected in 26,000 µg/L in well TMW-5 (in the former UST area), 17,000 µg/L in boring B-2 immediately adjacent TMW-5, and 14,000 µg/L in boring B-1 just southwest of the former UST area. Elevated benzene concentrations (>1,000 µg/L) have been detected southwest of the former UST area (MW-1, MW-3, MW-6 and SB-5), and north of the former UST (MW-2).

The horizontal extent of the dissolved hydrocarbon plume has been adequately characterized in all directions except the southwest and eastern directions. Groundwater analytical results from offsite borings SB-1, SB-3 and SB-4 (1997) and perimeter borings SB-1, SB-2 and SB-6 (2001) suggest that little or no hydrocarbons have not migrated north, east and south of the site. No hydrocarbons were detected in groundwater samples from borings SB-1, SB-3, SB-4, SB-6, and low concentrations were detected in onsite borings SB-1 and SB-2. With the recent detection of SPH in TMW-4, the hydrocarbon plume is not adequately characterized in the eastern direction. With benzene and other hydrocarbons detected in each of the five borings/wells along the southwestern property boundary, the extent of dissolved hydrocarbons is not adequately characterized in the southwest direction. Offsite assessment in this direction has been constrained by the large building on the adjacent property.

5.0 RISK EVALUATION

To evaluate the potential risk from residual hydrocarbons, Cambria conducted a risk evaluation using the RWQCB guidance document *Application of Risk Based Screening Levels and Decision Making to Sites With Impacted Soil and Groundwater* (RWQCB 2001). To conduct the risk evaluation, Cambria compared residual contaminant concentration data to Tier 1 Risk Based Screening Levels (RBSLs) ('final RBSLs') established by the RWQCB. For constituents whose residual concentrations exceed the Tier 1 RBSLs, Cambria conducted a Tier 2 risk evaluation in

accordance with the RWQCB guidance document. The Tier 2 risk evaluation involves modifying the Tier 1 RBSLs based on site-specific considerations. This risk evaluation can assist with the establishment of target cleanup levels for residual contaminants in soil and groundwater. This risk evaluation does not consider or apply to SPH present in the site subsurface.

5.1 Soil

Soil analytical results and select RBSLs for the COCs are summarized on Table 2. Table 2 shows the Tier 1 *final* RBSLs for both residential and commercial categories where site groundwater is not considered a current or potential drinking water resource. Cambria included the residential RBSLs due to the presence of residences north of the site; the building southwest of the site is commercial. Table 2 also shows the 'Tier 2' RBSLs for indoor air impacts, for residential and commercial categories. Cambria presents the RBSLs for surface soil (≤3 meters bgs). The RBSLs for *sub*surface soil (>3 meters bgs) are identical or similar to the surface soil RBSLs and would be applicable to most soil analytical results which are >3 meters bgs.

Petroleum hydrocarbon concentrations in soil exceeding the Tier 1 RWQCB RBSLs for surface soil have been detected in several borings at the site. As shown on Table 2, concentrations of TPHg, TOG, benzene, ethylbenzene and xylenes in some borings exceed the commercial Tier 1 final RBSLs. Figures 8 and 9 present the historical TPHg and benzene concentrations in soil, respectively, with concentrations exceeding the commercial final RBSL shown in bold. TPHg and benzene concentrations exceeding the Tier 1 final RBSLs are located nearby the former UST area, with one benzene RBSL exceedance further from the former UST area, located along the southwest property boundary at 20 feet bgs in SB-5 (2001).

To conduct a 'Tier 2' evaluation, Cambria considered modifying Tier 1 RBSLs based on site-specific considerations. All the final RBSLs (except for benzene) are derived for the risks associated with petroleum hydrocarbons leaching from soil into groundwater. Since the impacted soil is primarily in the capillary fringe/saturated zone, and since groundwater data is present, Cambria assumes that soil leaching is not a regulatory concern. With the site fully paved and no nearby ecological receptors, Cambria assumes that the RBSL protective of indoor air impact would be the appropriate RBSL for the site. Again, the indoor air impact RBSLs for residential and commercial site use are summarized on Table 2. If indoor air impact is considered the only potential completed pathway for exposure to residual compounds, only select benzene

concentrations exceed the indoor air impact RBSL (commercial use). Figure 9 presents benzene concentrations exceeding the indoor air impact RBSL, which is the same as the Tier 1 RBSL for benzene. These exceedences are located near the former USTs and along the southwest property boundary at 20 feet bgs. No RBSLs for indoor air impacts are established for TPH compounds in soil.

5.2 Groundwater

Groundwater analytical results and select RBSLs for the COCs are summarized on Table 3. Table 3 shows the Tier 1 *final* RBSLs for sites where groundwater is not considered a current or potential drinking water resource. Table 3 also shows the 'Tier 2' RBSLs for indoor air impacts. The groundwater RBSLs are not differentiated into residential and commercial categories.

Petroleum hydrocarbon concentrations in groundwater exceeding the Tier 1 RWQCB RBSLs for surface soil have been detected in several borings/wells at the site. As shown on Table 3, concentrations of TPHg, TOG, benzene, toluene, ethylbenzene, xylenes, and MTBE in some groundwater samples exceed the commercial Tier 1 final RBSLs.

To conduct a 'Tier 2' evaluation, Cambria considered modifying Tier 1 RBSLs based on site-specific considerations. The site Tier 1 final RBSLs are derived for the risks associated with protection of aquatic life. With the site fully paved and no nearby ecological receptors, Cambria assumes that the RBSL protective of indoor air impact would be the appropriate RBSL for the site. Again, the indoor air impact RBSLs are summarized on Table 3. No RBSLs for indoor air impacts are established for TPH compounds in groundwater.

If indoor air impact is considered the only potential completed pathway for exposure to residual compounds, only select benzene concentrations exceed the indoor air impact RBSL. Because site surface soil consists primarily of clay, Cambria used the benzene RBSL associated with fine-grained soil (5,800 µg/L) rather than coarse-grained soil (84 µg/L). Figure 10 presents benzene concentrations exceeding the indoor air impact RBSL. The benzene RBSL exceedences are located primarily near the former UST area (TMW-5, B-1 and B-2). While RBSL exceedences were also detected along the southwest property boundary in a grab sample from boring SB-5, groundwater samples from nearby monitoring well MW-3 are likely more representative of dissolved benzene concentrations near the southwest boundary of the site.

6.0 CONCLUSIONS

Cambria concludes the following based on our review of the site conditions:

1. Separate-phase hydrocarbons and elevated concentrations of petroleum hydrocarbons are present in site soil and groundwater. These petroleum hydrocarbons are primarily TPHg and BTEX compounds, and TOG near the former used oil UST location. Although MTBE has been detected sporadically in groundwater, MTBE has not been confirmed by EPA Method 8260 analysis. If MTBE is confirmed in the subsurface, the MTBE would likely be from another source since the USTs were removed in 1988 prior to common MTBE use.

2. The site hydrogeology consists of primarily of clays and silts with interbedded higher permeability sand and gravel layers to the total depth explored of 36 feet bgs. The two sand units (upper and lower) may be discontinuous, and may be confined or unconfined by the clay layers. The groundwater flow direction at the site has varied historically, generally flowing either northwestward or radially outward from the center of the site. A radial groundwater flow direction could be explained by water mounding within the UST excavation cavity or from the apparent screening of some site wells across the two water-bearing sand units. Cambria has concluded that wells MW-1 and MW-3 appear to be screen across two water-bearing units, wells MW-2 and TMW-4 may be screened into two water-bearing units, and all site well screens are often fully submerged by site groundwater.

3. Separate-phase hydrocarbons (i.e., free product) have been detected in all six site wells and are likely primarily located in the capillary fringe area and submerged in the upper sandy unit at the site. SPH thickness is typically greatest when groundwater levels decrease and expose the SPH, although SPH thickness is greatest in well MW-2 when the groundwater level rises into the upper sand unit. The recent detection of SPH in perimeter site wells TMW-4 and MW-6 for the first time suggests that the SPH plume in not stable.

4. Petroleum hydrocarbons in soil are primarily located in the capillary fringe and saturated zone at depths ranging from approximately 10 to 25 feet bgs, with the highest concentrations detected north and northwest of former UST excavation area and elevated benzene concentrations southwest of the former USTs. Shallower unsaturated soil has presumably been remediated by site excavation activities. The lateral extent of hydrocarbons in soil

appears to be adequately defined by onsite and offsite borings in all directions, except for benzene in the west and southwest directions.

5. Hydrocarbons are present in groundwater across most of the site, with the highest concentrations near the former UST area. The horizontal extent of the dissolved hydrocarbon plume has been adequately characterized in all directions except the southwest and eastern directions. With the recent detection of SPH in TMW-4, the hydrocarbon plume is not adequately characterized in the eastern direction. With benzene and other hydrocarbons detected in each of the five borings/wells along the southwestern property boundary, the extent of dissolved hydrocarbons is not adequately characterized in the southwest direction. Offsite assessment in this direction has been constrained by the large building on the adjacent property.

6. Results of the conduit study indicate that dissolved hydrocarbons and SPH are migrating toward the 75-inch diameter storm drain beneath Miller Avenue located approximately 60 feet from site well MW-6. This storm drain, located at approximately 13 to 16 feet bgs, apparently intersects groundwater year-round, is fully submerged by groundwater periodically, and could be located within the upper sandy water-bearing unit. Groundwater analytical results from offsite boring SB-1, located between the site and the storm drain, suggest that hydrocarbons have not migrated offsite toward the offsite storm drain.

7. Our risk evaluation indicates while TPH, TOG and BTEX concentrations in soil and groundwater exceed Tier 1 RBSLs, only *benzene* exceeds the proposed 'Tier 2' RBSLs based on site-specific considerations. The proposed Tier 2 RBSL for benzene is the RBSL for indoor air impact. The Tier 2 RBSL exceedences for benzene are located nearby the former UST area and along the southwest property boundary at 20 feet bgs.

8. Although SPH and elevated petroleum hydrocarbons are present in the site subsurface, the migration and exposure to residual hydrocarbons can be managed. The current site capping by the building foundation and site pavement helps manages the risk. Site remediation would abate residual hydrocarbons and further reduce the risk associated with the subsurface hydrocarbons.

7.0 RECOMMENDED ACTIVITIES

Based on our conclusions for the site, Cambria offers the recommendations presented below.

7.1 Additional Investigation, Well Replacement, and Well Surveying

Cambria recommends preparation of a workplan to further define the extent of hydrocarbons at the site. The proposed investigation would assess offsite soil and groundwater south and east of the site, beyond the recent observation of free product in site wells TMW-4 and MW-6. The investigation would further evaluate conditions between the site and the 75-inch diameter storm drain beneath Miller Avenue, which could act as a conduit for hydrocarbon migration. The investigation would include continuous coring to further evaluate soil hydrogeology and the depth of SPH. The workplan would also evaluate the existing well screen intervals and propose abandonment and replacement of wells. Finally, the investigation workplan would propose well installation for feasibility testing (recommended below). In conjunction with the additional investigation, Cambria recommends surveying of wells MW-3 and TMW-4 (and any new wells) to the City of Oakland datum. The other site wells have been surveyed to the Oakland datum, while wells MW-3 and MW-4 are presumably surveyed to NGVD 29 datum, which is approximately 3 feet higher than the Oakland datum.

7.2 Feasibility Testing

To facilitate evaluation of appropriate remedial alternatives, Cambria recommends conducting a feasibility test. The feasibility test would most likely use dual-phase extraction techniques to assess hydrocarbon recovery rates, vapor flow rates, groundwater extraction rates, SPH recovery rates and thickness in the formation, and radius of influence. Results of the feasibility testing would be used in preparation of a corrective action plan for site remediation. Cambria recommends preparation of a feasibility test plan in conjunction with the investigation workplan.

7.3 Interim Remedial Activities

Because of the unstable SPH plume and the continued presence of SPH in site wells, Cambria recommends implementing hydrocarbon recovery using passive skimmers and hand bailing. During the recent monitoring event Cambria hand bailed approximately 13.5 liters of SPH from

site wells. To enhance SPH recovery, Cambria recommends installing passive SPH skimmers in wells MW-1 and MW-2, which have historically contained the highest SPH thickness at the site. The passive skimmers consist of an active buoy assembly designed to remove free product to a sheen. The buoy allows free product but not water to collect in the 2 liter (0.53 gallon) collection canister. The buoy system is equally effective with water table fluctuations as great as 24 inches.

Cambria proposes hand bailing of the remaining site wells that contain SPH. Cambria proposes monitoring/emptying of the skimmers and hand bailing on a monthly basis during the winter and spring months, and on a semi-monthly (every two weeks) during the dry summer and fall months. The monitoring, emptying and bailing schedule would be modified as dictated by the actual SPH recovery rates in the individual wells. SPH recovery may be discontinued upon implementation of a more permanent corrective action.

7.4 Quarterly Monitoring and Sampling

Cambria recommends continued quarterly groundwater monitoring to further evaluate SPH thickness, groundwater flow direction, and plume stability. All groundwater wells will be gauged and inspected for SPH on a quarterly basis. Groundwater samples will be collected from site wells without SPH and analyzed for TPHg by modified EPA Method 8015, and BTEX and MTBE by EPA Method 8020, with confirmation analysis for detectable MTBE by EPA Method 8260. Quarterly groundwater monitoring and SPH removal reports will be prepared.

Fuel Leak Case No. RO0000327

Dear Mr. Gholami:

On behalf of Mr.'s Aaron and Stanley Wong, Cambria Environmental Technology, Inc. (Cambria) has prepared this *Site Summary, Conduit Study and Monitoring Report* for the site referenced above. As requested by the Alameda County Health Care Services Agency, this report incorporates fourth quarter 2002 monitoring results.

We look forward to working with you on this project. If you have any questions or comments, please contact me at (510) 420-3307 or Mr. Bob Clark-Riddell at (510) 420-3303.

Sincerely,
Cambria Environmental Technology, Inc.

Mary C. Holland-Ford
Project Geologist

cc: Mr. Stanley Wong, 2200 East 12th Street, Oakland, California 94606

Abbreviations and Notes:

1,300 = concentrations exceeding commercial final RBSLs shown in bold.

TPHg = Total petroleum hydrocarbons as gasoline

Benzene, Toluene, Ethylbenzene, Xylenes by EPA Method 8020, and by 8260 if in parenthesis

MTBE methyl tert butyl ether by EPA Method 8020

VOCs = volatile organic compounds by EPA Method 8260

ND = not detected above laboratory detection limits

ND* = not detected with the exception of reported concentrations for benzene, toluene, ethylbenzene and xylenes

HVOCs = halogenated volatile organic compounds by EPA Method 8010

mg/kg = Milligrams per kilogram

<n = Below detection limit of n mg/kg

-- = Not analyzed

Residential RBSLs = Table B-1 - Risk Based Screening Level Components for Surface Soil (Potentially Impacted Groundwater is not a Current or Potential Source of Drinking Water) for commercial/industrial reuse for established by the SFBRWQCB, Interim Final December 2001. (The risk driver is also shown). MTBE RBSL for coarse soil (fine soil).

Commercial RBSLs = Table B-2 - Risk Based Screening Level Components for Surface Soil (Potentially Impacted Groundwater is not a Current or Potential Source of Drinking Water) for commercial/industrial reuse for established by the SFBRWQCB, Interim Final December 2001. (The risk driver is also shown). MTBE RBSL for coarse soil (fine soil).

RBSLs for indoor air = Tables B-1 and B-2 from SFBRWQCB above, Interim Final December 2001

Risk Driver							aquatic life	aquatic life	aquatic life	aquatic life	aquatic life	aquatic life	aquatic life	
RBSL - Indoor Air Impact							NE	84 (5800)	76000 (530000)	170,000	150000 (160000)	50000(4.9E+05)	NE	N/A

Abbreviations and Methods:

bgs = below grade surface
(ug/L) = micrograms per Liter
Depth to GW = Depth to groundwater relative to top of casing
SPH = Separate phase hydrocarbons
TOG = Total oil and grease by modified EPA Method 3550
TPHg = Total petroleum hydrocarbons as gasoline by modified EPA Method 8015
Benzene, Toluene, Ethylbenzene, Xylenes by EPA Method 8020, and by 8260 if in parenthesis
MTBE methyl tert butyl ether by EPA Method 8020
VOCs = volatile organic compounds by EPA Method 8260
ND* = not detected with the exception of reported concentrations for benzene, toluene, ethylbenzene and xylenes
GW Elevation = Groundwater elevation in relation to mean sea level; calculated according to the relationship GW elevation = TOC - DTW + (0.8)(SPH thickness)
a = Relative to site datum established by Earth Systems Engineering
b = Top of casing elevation surveyed 8/10/93 by professional engineer (assumed based on NGVD 29 datum that is approximately 3 feet higher than City of Oakland datum)
c = Top of casing elevation surveyed 6/13/01 to City of Oakland datum by Renner Survey Company of Burlingame, CA. for Sequoia Environmental. Wells MW-3 and MW-4 were not surveyed
d = Casing damaged during excavation activities; not surveyed
e = Assumed top of casing elevation relative to City of Oakland datum, estimated by subtracting 3.00 feet from previous elevation presumably from NGVD 29 datum
1,300 = concentrations exceeding commercial final RBSLs (not a potential drinking water resource) shown in bold
Final RBSL - Potential Drinking Water Source = Table F-1 - Components for Groundwater Screening Levels (Groundwater is not a Current or Potential Drinking Water Resource) established by the SFRWQCB, Interim Final December 2001. (The risk driver is also shown)
Final RBSL - Not A Potential Drinking Water Source = Table F-2 - Components for Groundwater Screening Levels (Groundwater is not a Current or Potential Drinking Water Resource) established by the SFRWQCB, Interim Final December 2001. (The risk driver is also shown).
RBSLs for indoor air = Tables F-1 and F-2 from SFRWQCB above, Interim Final December 2001

Table 4. **Well Completion Data** - Credit World Auto Sales, 2345 International Boulevard, Oakland, California

Well No.	Installation Date	Boring Diameter (inches)	Well Diameter (inches)	Screen Size (inches)	Total Depth (feet bgs)	Surface Seal (feet bgs)	Sand Pack Interval (feet bgs)	Screened Interval (feet bgs)

							Hydrocarbons removed by bailing or purging (lbs.) =		*91.38*
							Hydrocarbons removed by free product removal system (see Note 1) (lbs) =		*30.5*
							Total estimated hydrocarbons removed (lbs) =		*121.88*

1. Tank Protect reported that the continuous free product removal system removed approximately 3 to 5 gallons between 8/20/97 and 1/14/98.
SPH Removal data provided for 5/23/01, 6/13/01, and 12/27/02 data.
bgs = below ground surface
When data is unavailable, hydrocarbon removal volume prior to 12/27/2002 is estimated by multiplying the well casing area (2" diameter casing = 0.60L/ft) by SPH thickness (feet)

CHAIN OF SAMPLE CUSTODY RECORD

Collector: Tanner Shah Date Sampled: 10-03-88 Time: 2-3:30PM

Location of Sampling: 2345 East 14th Street, Oakland, CA

Project Number: CEC/SBW 9.8.2 Survey Number:

Sample Type: Grab Ground Water

Container Type and Condition: Six number 40ml VOA's

Contract Laboratory Record/Name: Sequoia Analytical Lab, 2549 Middlefield Rd, Redwood City CA 94063

Sample ID	Field Information
B_1-W	Grab Ground Water Sample from boring B_1
B_2-W	Grab Ground Water Sample from boring B_2
B_3-W	Grab Ground Water Sample from boring B_3

Analysis Requested: (I) Analyse Water Samples B_1-W and B_2-W
(1) TPH G by EPA Test Method 5030
(2) B, T, X & C by EPA Test Method 602

(II) Analyse water Sample B_3-W by:
(1) EPA Method 5030 and

Results Needed By: (2) EPA 601 (3) EPA 602, (4) EPA 503 A & E.

Mr. Marc Zomorodi
Tank Protect Engineering
2821 Whipple Road
Union City, California 94587

Dear Mr. Zomorodi:

Trace Analysis Laboratory received six soil samples on July 26, 1993 for your Project No. 267C072393, Credit Auto World (our custody log number 3465).

These samples were analyzed for Total Petroleum Hydrocarbons as Gasoline and Benzene, Toluene, Ethylbenzene, and Xylenes. Our analytical report and the completed chain of custody form are enclosed for your review.

Trace Analysis Laboratory is certified under the California Environmental Laboratory Accreditation Program. Our certification number is 1199.

If you should have any questions or require additional information, please call me.

Sincerely yours,

Scott T. Ferriman

DATE: 8-20-93

Drilling will continue inside the conductor casing, with a drill bit of smaller diameter than the conductor casing. If additional known aquifers are to be fully penetrated, the procedure will be repeated with successively smaller diameter conductor casings.

The bottom of the well screen in a confined aquifer will be determined by presence or lack of a clay layer or aquitard as described above. The screened interval in a confined zone shall extend across the entire saturated zone of the aquifer or up to a length of 20 feet, which ever is less. The screened zone and filter pack will not cross-connect to another aquifer.

CONSTRUCTION MATERIALS

Casing and Screen Materials: Well casing and screen will be constructed of clean materials that have the least potential for affecting the quality of the sample. The most suitable material for a particular installation will depend upon the parameters to be monitored. Acceptable materials include PVC, stainless steel, or low carbon steel.

Casing Joints: Joints will be connected by flush threaded couplers. Organic bonding compounds and solvents will not be used on joints.

Well Screen Slots: Well screen will be factory slotted. The size of the slots will be selected to allow sufficient groundwater flow to the well for sampling, minimize the passage of formation materials into the well, and ensure sufficient structural integrity to prevent the collapse of the intake structure.

Casing Bottom Plug: The bottom of the well casing will be permanently plugged, either by flush threaded screw-on or friction cap. Friction caps will be secured with stainless steel set screws. No organic solvents or cements will be applied.

Filter Pack Material: Filter envelope materials will be durable, water worn, and washed clean of silt, dirt, and foreign matter. Sand size particles will be screened silica sand. Particles will be well rounded and graded to an appropriate size for retention of aquifer materials.

conditions or local regulations require. Drilling mud, when used, will be thinned prior to packplacement. The sand pack shall cover the entire screened interval and rise a minimum of 2 feet above the highest perforation.

Bentonite Seal Placement: A bentonite seal will be placed above the sand pack by a method that prevents bridging. Bentonite pellets can be placed by free fall if proper sinking through annular water can be assured. Bentonite slurry will be placed by the tremie pipe method from the bottom upward. The bentonite seal will not be less than 1 foot in thickness.

Grout Seal Placement: The cement grout mixture will be hydrated with clean water and thoroughly mixed prior to placement. If substantial groundwater exists in the bore hole, the grout shall be placed by tremie pipe method from the bottom upward. In a dry borehole, the grout may be surface poured to a depth of 30 feet. Below a depth of 30 feet grout will be placed by tremie pipe. Grout will be placed in 1 continuous lift and will extend to the surface or to the well vault if the well head is completed below grade. A minimum of 5 feet of grout seal will be installed, unless impractical due to the shallow nature of the well.

Surface Completion: The well head will be protected from fluid entry, accidental damage, unauthorized access, and vandalism. A watertight, locking cap will be installed on the well casing. Access to the casing will be controlled by a keyed lock.

Well heads completed below grade will be completed in a concrete and/or steel vault, installed to drain surface runoff away from the vault.

Well Identification: Each well will be labeled to show well number, depth, hole and casing diameter, and screened interval.

LOG OF EXPLORATORY BORING

PROJECT NUMBER 267 — BORING NO. SB-1

PROJECT NAME 2345 E. 14th Street, Oakland CA — PAGE 1

BY LNH — DATE 4/21/97 — SURFACE ELEV. 27 FT

RECOVERY (FT/FT)	OVA (PPM)	PENETRATION (BLOWS/FT)	GROUND WATER LEVELS	DEPTH IN FT.	SAMPLES	LITHOGRAPHIC COLUMN	DESCRIPTION
							ASPHALT
							AGGREGATE BASE (GW): Brown, dry, no odor.
							CLAY (CL): Black mottled green, scattered sand, silty, dry, no odor.
1.3/2.0	10	--		5			SAND (SP): Brown, fine-grained, moist to very moist, no odor.
.50/2.0	--	--		10			
1.5/2.0	10	--		15			
							CLAYEY SAND (SC/SP): Brown, medium-grained, dry to moist, no odor.
2.0/2.0	8	--		20			
1.5/2.0	--	--		25			
							Boring terminated at 32 feet. Boring sampled to 32 feet. No water level was obtained due to caving.
2.0/2.0	2	--		30			
				35			

REMARKS: Drilled using the "GeoProbe method", 2.0 inch diameter boreholes. Samples collected in 1.0-inch by 6.0-inch acetate tubes.

LOG OF EXPLORATORY BORING

PROJECT NUMBER 267 BORING NO. SB-2

PROJECT NAME 2345 E. 14th Street, Oakland CA PAGE 1

BY LNH DATE 4/21/97 SURFACE ELEV. 27 FT

RECOVERY (FT/FT)	OVA (PPM)	PENETRATION (BLOWS/FT)	GROUND WATER LEVELS	DEPTH IN FT.	SAMPLES	LITHOGRAPHIC COLUMN	DESCRIPTION
							ASPHALT
							AGGREGRATE BASE (GW): Brown, dry, no odor.
							CLAY (CL): Brown, green at 11.5 feet, silty, stiff, dry to moist, hydrocarbon ordor at 11.5.
1.3/2.0	8	–		5			
2.0/2.0	46	--	▽	10			
							CLAYEY SAND (SC/CL): Green, fine to medium-grained, moist, hydrocarbon odor.
2.0/2.0	340	–		15			
2.0/2.0	8	–		20			
							SAND (SP): Brown, clayey, fine-grained, moist, no odor.
1.0/2.0	8	--		25			
							CLAYEY SAND (SC/SP): Brown, fine-grained, wet, no odor.
2.0/2.0	21	–		30			Boring terminated at 32.0 feet. Boring sampled to 32.0 feet.
				35			

REMARKS: Drilled using the "GeoProbe method", 2.0 inch diameter boreholes. Samples collected in 1.0-inch by 6.0-inch acetate tubes.

LOG OF EXPLORATORY BORING

BY LNH | DATE 5/1/97 | SURFACE ELEV. 27 FT

RECOVERY (FT/FT)	OVA (PPM)	PENETRATION (BLOWS/FT)	GROUND WATER LEVELS	DEPTH IN FT.	SAMPLES	LITHOGRAPHIC COLUMN	DESCRIPTION
							ASPHALT
							SANDY CLAY (CL/SC): Brown motteled green, stiff, dry, no odor.
2.0/2.0	12	–		5			
1.5/2.0	4	–		10			
							CLAYEY SAND (SC/CL): Brown, organics, fine to medium grained, dry to moist, no odor.
2.0/2.0	6	–		15			
1.5/2.0	14	–		20			
2.0/2.0	4	–		25			
							Boring terminated at 27.0 feet. Boring sampled to 27.0 feet.
				30			
				35			

REMARKS: Drilled using the "GeoProbe method", 2.0 inch diameter boreholes. Samples collected in 1.0-inch by 6.0-inch acetate tubes.

LOG OF EXPLORATORY BORING

PROJECT NUMBER 267 — BORING NO. SB-5

PROJECT NAME 2345 E. 14th Street, Oakland CA — PAGE 1

BY LNH — DATE 5/1/97 — SURFACE ELEV. 27 FT

RECOVERY (FT/FT)	OVA (PPM)	PENETRATION (BLOWS/FT)	GROUND WATER LEVELS	DEPTH IN FT.	SAMPLES	LITHOGRAPHIC COLUMN	DESCRIPTION
							CONCRETE
							AGGREGATE BASE (GW): Brown, dry, no odor.
							CLAY (CL): Grey to black, sandy, soft, no odor.
1.0/2.0	12	–		5			
							CLAYEY SAND (SC/CL): Green, fine-grained, dry, hydrocarbon odor.
2.0/2.0	67	–		10			
2.0/2.0	6	–		15			CLAYEY SAND (SC/CL): Brown, fine-grained, moist, no odor.
							SANDY CLAY (CL/SC): Brown, organics, stiff, dry no odor.
2.0/2.0	11	–		20			
							CLAYEY SAND (SC/CL): Brown, fine-grained, wet at 27.0 feet, no odor.
2.0/2.0	6	–		25			
							Boring terminated at 27.0 feet. Boring sampled to 27.0 feet. A hydrocarbon sheen on the groundwater was observed.
				30			
				35			

REMARKS: Drilled using the "GeoProbe method", 2.0 inch diameter boreholes. Samples collected in 1.0-inch by 6.0-inch acetate tubes.

* water and vapor samples are reported in ug/L, wipe samples in ug/wipe, soil and sludge samples in mg/kg, and all TCLP and SPLP extracts in ug/L

cluttered chromatogram; sample peak coelutes with surrogate peak

*The following descriptions of the TPH chromatogram are cursory in nature and McCampbell Analytical is not responsible for their interpretation: a) unmodified or weakly modified gasoline is significant; b) heavier gasoline range compounds are significant(aged gasoline?); c) lighter gasoline range compounds (the most mobile fraction) are significant; d) gasoline range compounds having broad chromatographic peaks are significant; biologically altered gasoline?; e) TPH pattern that does not appear to be derived from gasoline (?); f) one to a few isolated peaks present; g) strongly aged gasoline or diesel range compounds are significant; h) lighter than water immiscible sheen is present; i) liquid sample that contains greater than ~5 vol. % sediment; j) no recognizable pattern.

FAX TRANSMITTAL

To: Ernie Date: 3/17/03

Company: N/A FAX No: 510-525-1011

From: Robert Shellman Re: 1093-01

Subject: Datum

NUMBER OF PAGES TRANSMITTED INCLUDING TRANSMITTAL SHEET:2

Ernie; The current datum that the topo is on is a local Oakland city datum.

To convert to NGVD29' add 3ft to each elevation.

Robert
