RE: Desert Petroleum station #793 4035 Park Boulevard Oakland, CA

Dear Mr. Levi:

My letter of January 12 contained a typographic error that needs to be corrected. The vapor extraction systems were started up on December 13, not on December 18 as stated in my earlier letter. It has also been brought to my attention that there were two glitches in the text of the report. It appears the computer repeated and deleted lines for some as yet unknown reason. Enclosed is a corrected copy; please dispose of the first report. I apologize for any inconvenience this may have caused you.

If you have any questions or concerns, please give me a call.

Sincerely,

Wendy J. Wittl

Senior Project Geologist

RE: Desert Petroleum station #793 4035 Park Boulevard Oakland, CA

Dear Mr. Levi:

On behalf of Desert Petroleum, Remediation Service Int'l is submitting the Site Assessment and Remediation Report. The enclosed report covers all of the site assessment and remediation work completed as of January 12, 1990. Remediation efforts have been continuous since December 18, with two vapor extraction systems operating to reduce vapors concentrations in the sewer and on-site. A status report will be submitted on February 15, covering the systems operation in the months of December, 1989 and January, 1990.

Statting depth :

If you have any questions or concerns, please give me a call.

Sincerely,

Wendy J. Wittl

Senior Project Geologist

1.0 INTRODUCTION

Desert Petroleum's station no. 793 (branded Beacon) is located at 4035 Park Boulevard in the City of Oakland, Alameda County, California (Figures 1 and 2). It is a retail fuel station which has been leased to Mr. Jason Golpad who operates the station under the name of J & M's Beacon Service Station. On November 30, 1989, Desert Petroleum was notified by the Alameda County Health Department (ACHD) that gasoline was leaking into a sewer on Brighton Avenue (Figure 2), near the station. This report details the work that has been done to: determine the source of the gasoline leak, to stop the leakage of gasoline, to assess the extent of contamination due to leakage of gasoline and to remediate any contamination due to the leakage of gasoline.

2.0 SITE DESCRIPTION

The station is located at the intersection of Park Boulevard and Hampel Road in a predominantly residential neighborhood (Figure 2). It is on the flank of a hill which slopes approximately 10 degrees to the west. The ground surface of the station itself is fairly level due to grading and a deck which is located at the western corner of the station (Figure 3). Based on the U.S.G.S. topographical map of the area, the surface elevation of the station is approximately 240 feet above mean sea level (MSL). There is an approximate 12 foot drop from the surface of the deck, at the far western corner of the station, to the ground surface below. The area beneath the deck is enclosed, similar to a sub-basement, and access to the area beneath the deck can be

gained from the driveway which parallels the northwest property line of the station.

Improvements at the station consist of a building, two pump islands, a waste oil tank, and three underground fuel storage tanks (Figure 3). The underground fuel storage tanks consist of an 8,000 gallon tank for regular leaded gasoline, a 10,000 gallon tank for regular unleaded gasoline and an 8,000 gallon tank for super unleaded gasoline. The age of the tanks is unknown, but is thought to be approximately 20 years. They are steel and were relined approximately four years ago. When the tanks were relined, the associated piping was also replaced.

3.0 BACKGROUND

On Thursday, November 30, 1989, Mr. Ariu Levi of the Alameda
County Health Department notified Desert Petroleum that gasoline
was trickling into a sewer on Brighton Avenue through a crack
in the bottom of the sewer manway. This was discovered due to
a homeowner in the area reporting the smell of gasoline vapors.

Desert Petroleum's area manager was sent to the site on November
30 to reconstruct and audit tank inventories and sales records.

The audit indicated overages on all tanks.

On Friday, December 1, 1989, Mr. Jason Golpad, the site operator, was contacted by Desert Petroleum and advised to test the fuel tanks and associated lines using an approved testing company and system.

On Wednesday, December 6, 1989, the underground storage tanks were tested. The results of these tests were inconclusive. The tank tester advised that additional testing and time would be required for conclusive results. Desert Petroleum decided further testing was not appropriate and considered it important to have the tanks emptied immediately to prevent any possible further release of product.

On Thursday, December 7, 1989 all fuel was removed from the underground storage tanks. However, the retail fueling facility had already been closed on December 5. The supply lines were pressure tested by Walton Engineering. The regular leaded and super unleaded lines passed but the regular unleaded supply line failed. Further investigation on this date verified a 1/2 inch hole in the 2 inch unleaded supply line beneath the eastern Also on Thursday, December 7, 1989, an ultrasound pump island. investigation was conducted to determine the location of the sewer lines. Figures 3 and 4 show the sewer lines, onsite and offsite respectively. In addition, an onsite soil gas investigation was also conducted. The results of the soil gas investigation found the site to be basically clean. There was one hot spot associated with the pump islands and there was some contamination associated with the located sewer line in the western corner of the property.

On Friday, December 8, 1989, Desert Petroleum filed an Unauthorized Release Report (Appendix B). Drilling permits for site assessment were obtained from the Alameda County Flood

Control and Water Conservation District, Zone 7 (Appendix C).

Underground Service Alert was notified and asked to locate lines on and near the site and around the sewer on Brighton Avenue (USA work order 334-954).

On Monday, December 11, 1989, drilling and soil sampling was initiated in order to assess possible contamination beneath the site and to provide wells for water sampling and remediation.

This work is discussed in detail in section 4.0 of this report labeled SITE INVESTIGATION.

On Tuesday, December 12, 1989, an encroachment permit was secured from the City of Oakland for assessment work on Brighton Avenue (Appendix D).

On Wednesday, December 13, 1989, active remediation was initiated. This is discussed in detail in section 5.0 of this report labeled REMEDIATION.

4.0 SITE INVESTIGATION

4.1 Investigative Procedures

Under the supervision of an RSI geologist, five soil borings were drilled onsite (RS-1, RS-2, RS-3, RS-5 and RS-6, Figure 3) and one boring was drilled near the sewer on Brighton Avenue (RS-4, Figure 2) on December 11, 12 and 13, 1989. Three of the borings onsite were completed as groundwater monitoring/extraction wells (RS-1, RS-5 and RS-6) and one of the borings was completed as a vapor extraction well (RS-2). During drilling operations, soil samples were collected every 5 feet starting at 5 feet beneath

ground surface (bgs) down to the total depth of each boring. The soil samples were used for laboratory analysis, field testing and soil description. The boring logs, a description of drilling and soil sampling operations and a well construction diagram are included in Appendix E. Table 1 presents well construction specifics.

All drilling was done by:

Datum Exploration
4300 Evora Road
Pittsburg, CA 94565
License Number 480802

After the groundwater monitoring/extraction wells were completed, they were developed and a groundwater sample was collected following the procedures outlined in Appendix F. Both soil and groundwater samples were transported to a state certified laboratory for analysis of benzene, toluene, ethylbenzene and xylenes (BTEX) and/or total petroleum hydrocarbons (TPH) using EPA methods 8020 and 8015.

All samples were analyzed by:

Superior Analytical Laboratory, Inc. 1385 Fairfax Street, Suite D San Francisco, CA 94124

Table 2 presents a summary of analytical results for soil samples and Table 3 gives a summary of analytical results for water

samples. The complete official results and chain of custody documents are included in Appendix G.

4.2 Findings - Soil

In general, the soils beneath the site, down to a depth of 40 feet, consist mainly of tan, brown or black clays, silty clays

These clayey soils often contain small amounts of gravel at depths of approximately 10 feet or deeper, but are generally tight and fairly plastic in nature. Some sandier soils were also found such as in the samples taken at 20 and 30 feet below ground surface (bgs) from RS-1 and 15 feet bgs from RS-2, which consisted of clayey sand with some gravel. The samples taken at 25 and 30 feet bgs from RS-5 also consisted of clayey sand and the sample taken at 25 feet bgs in RS-6 consisted of silty sand. Bedrock was not encountered during drilling operations. For more detailed soil descriptions see the boring logs in Appendix E.

RS-1 was drilled east of the pump island where the leaking supply line was found (Figure 3). It was drilled to a total depth of 30 feet and completed as a groundwater monitoring/extraction well. Laboratory analysis of soil samples from this boring indicated that the sample from 5 feet bgs had a TPH concentration of 16 parts per million (ppm) and the sample from 10 feet bgs had a TPH concentration of 33 ppm. The samples from 15 and 20 feet bgs contained no detectable TPH levels. However, there was some toluene (0.008 ppm) detected in the sample from 20 feet bgs (Table 2). The sample from 25 feet bgs had a TPH level of 10

ppm and all BTEX compounds were found in concentrations of less than 1 ppm. The samples from 30 feet bgs contained some toluene (0.012 ppm) but no benzene, ethylbenzene, xylenes or TPH was detected.

RS-2 was drilled northwest of the underground tanks to a depth of 20 feet and completed as a vapor extraction well. Only the sample from 10 feet bgs contained detectable TPH concentrations (11 ppm). The sample from 20 feet bgs was also analyzed for BTEX and 0.017 ppm of toluene was detected.

RS-3 was drilled near the storm drain in the southern corner of the property to determine if gasoline may have migrated along underground lines in that direction. It was drilled to a depth of 10 feet and subsequently abandoned. No detectable concentrations of TPH were found in the samples from 5 and 10 feet bgs. Low levels of toluene (0.043 ppm) and xylenes (0.008 ppm) were detected in the sample from 5 feet bgs. Toluene was also detected in the sample from 10 feet bgs at a concentration of 0.20 ppm.

RS-4 was drilled just east of the sewer manhole on Brighton Avenue in an attempt to penetrate gasoline saturated soils.

Nothing but fairly clean clay was penetrated and the boring was abandoned at a depth of 10 feet. The sample taken at 5 feet bgs had a TPH concentration of 50 ppm and BTEX concentrations ranging from 0.74 to 4.1 ppm (Table 2). The sample taken at 10 feet bgs

Site Assessment and Remediation Report January 5, 1990

had a TPH concentration of 8 ppm and BTEX concentrations ranging from 0.17 to 0.94 ppm.

RS-5 was drilled near the western corner of the station, as close as possible to the sewer line. It was drilled to a depth of 40 feet and completed as a groundwater monitoring/extraction well. No detectable concentrations of TPH were found in the samples from 5, 10 and 15 feet bgs. The sample from 20 feet bgs had a TPH concentration of 530 ppm and BTEX concentrations ranging from 1.5 ppm up to 22 ppm. The sample from 25 feet bgs contained much lower concentrations of hydrocarbons with a TPH concentration of only 4 ppm and BTEX concentrations ranging from 0.058 to 0.7 ppm. However, the TPH level in the sample from 30 feet bgs was much higher with a concentration of 1,600 ppm. No detectable concentration of TPH was found in the sample from 35 feet bgs and only 1 ppm of TPH was found in the sample from 40 feet bgs. The sample from 40 feet bgs was also analyzed for BTEX and contained only minor concentrations ranging from 0.009 to 0.069 ppm.

RS-6 was drilled in the northwest portion of the station in the downhill direction from the underground storage tanks. It was drilled to a depth of 35 feet and completed as a groundwater monitoring/extraction well. None of the soil samples contained detectable TPH concentrations. The samples from 20, 25 and 35 feet bgs were also analyzed for BTEX. No BTEX compounds were detected in these three samples in concentrations greater than 0.017 ppm (Table 2).

Due to the profusion of underground lines near the sewer manway on Brighton Avenue, the area northeast of the manway was excavated with a backhoe instead of using a drilling rig. The excavation uncovered three different underground lines. The uppermost line was a storm drain line that transects Brighton Avenue just southeast of the sewer manway. The storm drain line was encountered at approximately 2.5 to 3 feet deep. Beneath the storm drain line, at a depth of approximately 5 feet, the sewer line which connects to the station runs into the northwest side of the manway. Gasoline appeared to be seeping from the backfill around this sewer line. Beneath the sewer line, at a depth of approximately 6 feet, is a water main which runs along the north side of Brighton Avenue. Native soil beneath the water main and around the sewer manway consists of tight clay.

Soil from the excavation on Brighton Avenue was stockpiled at the station. It was piled on, and covered with, plastic sheeting.

Two grab samples were collected and analyzed from this spoils pile (samples SB-1 and SB-2, Table 2). SB-1 had a TPH concentration of 130 ppm and SB-2 had a TPH concentration of 370 ppm.

Prior to backfilling the excavation with pea gravel, an 8 foot section of perforated 4 inch PVC pipe was placed in the hole for use as an extraction well. This well is labeled as RS-7 on Figure 2.

4.3 Findings - Groundwater

Small amounts of groundwater were encountered beneath the station during drilling operations. Groundwater was first noticed in RS-1 at a depth of 20 feet after the boring had been drilled to 20 feet bgs on December 11, 1989 and left open overnight. A few inches had accumulated; more water accumulated in the boring as it was drilled on the following day to a total depth of 30 feet, where it was terminated in clayey sands. However, since none of the soil samples were saturated, it could not be determined from what depth the water was being produced. Depth to water measurements on December 14, 1989 indicated that the water table had stabilized in RS-1 at a depth of 24.25 feet (Table 4).

During drilling operations, water was first noticed in RS-5 at a depth of 35 feet. But, as in RS-1, none of the soil samples appeared to be saturated or capable of producing much water. However, RS-5 was the only well to produce even moderate amounts. Drilling was terminated at a depth of 40 feet in sandy clays. The measured depth to water in RS-5 on December 14, 1989 was 25.97 feet.

Wet, silty sands were encountered while drilling RS-6 between 20 and 25 feet bgs. These wet silty sands are underlain by damp clays, and the boring was terminated at a depth of 35 feet in silty clay. Very little water was produced while drilling. The measured depth to water in RS-6 on December 14, 1989, was 22.52 feet.

After the wells were completed, but before the traffic boxes were installed, they were allowed to stand overnight. On December 14, 1989, depth to water measurements were taken, the top of casing for all wells was surveyed, the wells were developed and water samples were collected.

The depth to water table measurements and top of casing survey were used to determine the water table elevation in each of the three groundwater monitoring extraction wells. The water table elevation in RS-1 was determined to be at 215.75 feet above MSL, in RS-5 it was 215.29 feet above MSL and in RS-6 it was 217.71 feet above MSL (Table 4). This information was used to construct and solve a three point problem. From this it was determined that on December 14, 1989 the groundwater gradient was towards the south and dropped approximately 4.5 feet per 100 feet (Figure 5).

All of the groundwater samples were found to contain elevated levels of hydrocarbons (Table 3). The sample from RS-1 had a TPH concentration of 19 ppm and BTEX concentrations ranging from 0.2 ppm up to 2.7 ppm. The sample from RS-5 contained 57 ppm of TPH and BTEX concentrations ranging from 0.67 ppm up to 4.3 ppm. The sample from RS-6 had a TPH concentration of 11 ppm and BTEX levels ranging from 0.16 ppm up to 1.7 ppm.

4.4 Conclusions

Soil contamination at this site appears to be fairly minimal.

As expected there are indications of soil contamination near

hydrocarbons in the samples from 5 and 10 feet bgs in RS-1. The site survey also indicated that there is probably soil contamination along the sewer line on the western side of the station. Although the tight soils beneath the station appear to have inhibited hydrocarbon migration, some vertical migration of hydrocarbons is suspected due to the high concentrations of hydrocarbons in the soil samples collected at 20 and 30 feet bgs from RS-5 and the hydrocarbon concentrations in the groundwater samples. Even though the soil samples taken at 25 feet bgs from RS-1 and RS-6 contained only minor concentrations of hydrocarbons, the groundwater samples from these two wells indicate that soil contamination may exist just above the water table beneath a portion of the site.

Groundwater appears to exist in thin perched layers in the more porous soils beneath the site. The groundwater samples from all three wells were found to contain elevated levels of hydrocarbons. Although the extent of groundwater contamination has not been determined, only a small volume of water appears to be involved. The direction of groundwater flow is not in the expected direction of the topography, and additional work is necessary to confirm the gradient.

It has been determined that one source of product leakage has been from the unleaded supply line beneath the eastern pump island. Due to the nature of the soil underlying the station (mostly tight clayey soils), it is suspected that product from this leak has migrated mostly along the underground lines beneath

this leak has migrated mostly along the underground lines beneath the station. The trenches in which underground lines are placed are generally backfilled with sand. This sand is much more porous than the native soils beneath the station and thus provides a conduit for the migration of liquids.

It is postulated that product from the supply line leak migrated down the supply line trench to the point where it intersects the pump electric line trench (Figure 3). From there it appears to have migrated along the electric line trench, beneath the building, to a point near the bathrooms where the electric line trench is thought to intersect a sewer line trench. From there it is postulated that the product followed the sewer lines (Figure 3 and 4), within the trench backfill, across and off the property and down to the sewer manway on Brighton Avenue, where it was leaking into the sewer manway due to a crack in the base of the sewer.

If product has migrated in the above described manner, soil contamination would be expected along the underground lines from the station down to the sewer. This suspected contamination probably does not extend far from the lines due to the nature of the native soils. As evident from soil samples taken during drilling, groundwater conditions south of the sewer on Brighton Avenue are monitored by RS-7.

tanks and the lines were pressure tested. On December 11, 12 and 13 the extraction wells were installed as previously discussed.

On December 13, 1989 a backhoe was brought in to excavate along the sewer on Brighton. A vacuum truck was also brought in and put on standby. During the excavation a 6 inch water main was broken. The water department had incorrectly marked the location of this line. Water from the main flooded the excavation and product also began to seep in and float on the water. The vacuum truck was used to pump out this fluid until the water department could fix the leak. Each load was manifested and sent to H & H Shipyard for treatment and disposal. Copies of these Hazardous Waste Manifests are contained in Appendix J. Soil from the excavation was stockpiled at the station for future remediation or disposal. After the excavation was backfilled, and RS-7 was constructed, the vacuum truck was used to withdraw fluids from RS-7 for approximately one week. Fluid volumes had decreased significantly by this time. Approximately 7,200 gallons of the fuel/wastewater mixture were removed from the excavation and RS-7.

During the excavation work on Brighton and the subsequent repair work, RSI's portable vapor extraction unit was used to extract and treat vapors from the sewer manway and the excavation. Since the construction of RS-7, the portable unit has been used during daylight hours to withdraw and treat gasoline vapors from this well. RSI's S.A.V.E. system was installed on the site on December 13, 14 and 15. It was connected to wells RS-1, RS-2, RS-5 and RS-6. For the first week it was in operation 24 hours

a day for vapor extraction and treatment. Due to noise and vibration problems it is currently being used only during daylight hours. Work is currently in progress to enclose and soundproof the system so it can be returned to around the clock operation.

5.2 Remediation Equipment

RSI's S.A.V.E. System (shown in Appendix H) and the portable vapor extraction unit are being used to remediate gasoline contaminated soils at this site. The S.A.V.E. equipment will also be used to remediate contaminated water as soon as the necessary permits are obtained.

The S.A.V.E. System is a blending of three separate types of remediation which are more efficient than the three systems alone. These systems are as follows:

- 1. Vapor extraction from soil.
- Spray aeration treatment of groundwater.
- 3. Thermal oxidation using an engine for combusting hydrocarbon-laden vapors and a catalytic converter to control emissions.

The soil vapor extraction system consists of a vacuum pump driven by an internal combustion engine. The engine powers a vacuum pump which is connected to one or more extraction wells. Placing a vacuum on the well, or wells, causes an air flow through the contaminated soil and into the well. The air flow causes the gasoline to be volatilized and entrained in the flow. The vapors

are drawn through the well and into the engine where they are burned as fuel. Generally a secondary fuel supply, either propane or natural gas, is necessary. The exhaust is then passed through a catalytic converter to insure complete combustion. Emissions from the engine, even when running on 100% gasoline vapors, meets the air quality standards for motor vehicle engines.

Groundwater contamination is remediated by use of a spray aerator. Spray aeration works on the same principle as an air stripper. In an air stripper, air is moved quickly over the surface of hydrocarbon laden water in order to volatilize the hydrocarbons. In spray aeration, hydrocarbon laden water is sprayed through the air inside a tank causing the hydrocarbons to volatilize. However, in the spray aerator there is no packing to foul or replace. To ensure sufficient hydrocarbon removal, the water is recirculated through a second set of spray nozzles. this part of the system, water-hydrocarbon separation is enhanced by both vacuum and heat. By lowering the air pressure, the Increasing the temperature at which hydrocarbons vaporize drops. temperature further increases the potential for hydrocarbons to vaporize. The RSI spray aerator takes advantage of both of these principles by spraying heated water in a vacuum. The engine provides the energy source for heating the water as well as powering the vacuum pump and downhole water pumps.

As the water level rises in the spray aerator tank from influx of water from the wells, a float will trigger a discharge of

an equal amount of remediated water. The level of contaminant reduction can be determined by sampling water influent and effluent. The treated water will then be passed through activated charcoal for final polishing before discharge. At an assumed recovery rate of 5 gpm, there will be an average of 20 cycles through the system before discharge. An 85% - 99% reduction in contaminants per cycle is the normal achieved rate, resulting in final removal rates approaching 100%.

Hydrocarbons extracted from the water in the spray aerator are combined with the vapors drawn out of the wells. The combined vapors are fed directly to the intake of the engine where they are combined with a secondary fuel (either propane or natural gas) and then burned in the engine. The exhaust is passed through a catalytic converter to insure complete combustion. Exhaust discharge from the engine, even when running on 100% gasoline vapors, meets the air quality standards for motor vehicle engines.

Because the entire system is under vacuum until vapors enter the cylinders of the engine for combustion, any possible leaks of seals or connections are into the system, resulting in no loss of hydrocarbons to the atmosphere. Since the engine is the power source for all other equipment, all systems stop when the engine stops. In addition, to provide for safe and secure operation of this equipment, the following safety elements have been designed into the system:

- 1. The engine has automatic shutoff features which will shut the entire system down if the engine should overheat or engine oil pressure drops below normal range.
- 2. The vacuum type fuel pump is mechanically driven by the engine; this ensures that when the engine stops running no more fuel will be pumped.
- 3. The hoses connecting the extraction wells to the equipment will run underground, when possible, through conduit.
- 4. All equipment, including the fuel tank, will be enclosed in a fenced compound.

RSI's portable vapor extraction system works the same as the S.A.V.E. System except that it is trailer mounted.

6.0 SUGGESTIONS AND RECOMMENDATIONS

The following is a list of suggestions and recommendations for further work at this site to further assess and remediate contamination caused by the release of hydrocarbons.

- 1. Further tank testing to determine if the tanks are tight

 with and replacement of the associated piping.
 - 2. Remeasure and survey the existing wells to confirm the direction of groundwater flow.
 - 3. Install shallow extraction wells into supply line trench backfill of underground lines onsite for connection to the S.A.V.E. equipment for vapor extraction. Part of this installation has already been completed.

Investigate the possible use of bionutrients which can then be injected into the trench backfill. The bionutrients will migrate along any transport paths and toward the sewer on Brighton Avenue. This will remediate, in situ, the soils along the sewer line and any other migration path.

4. Install slotted casing in spoils pile for onsite treatment by vapor extraction.

7.0 MONITORING

The time necessary to reduce gasoline concentrations in soil and groundwater to acceptable levels is site specific due to a number of complex variables. No estimation can be made as to the length of time it will take for remediation.

In order to track the progress of remediation, intake and exhaust vapor samples were taken as soon as possible after the system was put into operation. Until remediation is complete, additional samples will be collected. These vapor samples will consist of one sample from each well and a combined sample from the intake of the S.A.V.E. equipment. Exhaust samples will be taken as necessary to comply with the conditions of the emissions permit. The procedure for collecting vapor samples is discussed in Appendix I. The samples will be analyzed for TPH and BTEX by a state certified laboratory.

Groundwater samples from each well will be collected and analyzed for TPH and BTEX on a quarterly basis. Depth to water

measurements will also be taken on a quarterly basis. The amount of water withdrawn and the amount of water discharged will be monitored and recorded. Water discharge samples from the S.A.V.E. System will also be collected on a quarterly basis.

Other system operating parameters which will be monitored and recorded include: hours of operation, engine rpm, vacuum level and air flow. Analytical results of vapor samples, water samples and all other pertinent data will be included and discussed in Quarterly Monitoring reports.

8.0 SUMMARY

Desert Petroleum's station no. 793 is located at 4035 Park
Boulevard in the City of Oakland, Alameda County, California.

The station is leased to Mr. Jason Golpad. Gasoline from a
leak in the unleaded supply line at the station has apparently
migrated along underground service lines off the property, where
it is leaking into the sewer system via a crack in the sewer
manway. Tank and line tests were conducted to determine the
source of the leak and the tanks were subsequently emptied.

Water flushing of, and vapor extraction from, the sewer system have been done to alleviate the buildup of gasoline vapors.

Product was also recovered from the excavation and extraction well near the sewer manway on Brighton Avenue.

Six soil borings, five onsite and one near the sewer manway, were drilled and sampled to determine the probable extent of

Site Assessment and Remediation Report January 5, 1990

where all here regulte

soil contamination. A soil gas survey was also conducted. In general, soil contamination appears to be minimal.

Four groundwater monitoring/extraction wells and one vapor well were installed. Groundwater samples were collected and found to contain elevated levels of hydrocarbons. All wells onsite have been connected to RSI's S.A.V.E. remediation system for vapor extraction and treatment. Groundwater extraction and treatment 2 5 total will begin as soon as a discharge permit can be obtained. extraction and groundwater treatment is in progress via RS-7, near the sewer manway on Brighton Avenue, using RSI's portable vapor extraction unit.

A remediation method will be evaluated to determine if additional measures are needed to clean up soils along the underground lines between the station and the sewer manway.

Remediation efforts at this site will be closely monitored. Quarterly update reports will be submitted to update remediation and assessment activities.

LIMITATIONS 9.0

The discussion and recommendation presented in this report are based on the following:

- 1. The professional performance of the personnel who conducted the investigations.
- The observations of the field personnel. 2.

- The results of laboratory analyses performed by a state certified laboratory.
- 4. Any referenced documents.
- 5. Our understanding of the regulations of the State of California; also, if applicable, other local regulations.

The services performed by Remediation Service, Int'l have been conducted in a manner consistent with the level of care and skill ordinarily exercised by members of our profession currently practicing under similar conditions in the State of California.

Please note that contamination of soil and/or groundwater must be reported to the appropriate agencies in a timely manner. No other warranty, expressed or implied, is made.

DESCRIPTION OF BORING TECHNIQUES AND SAMPLING PROCEDURES

Under the supervision of a Remediation Service Int'l - (RSI) geologist, the soil borings are advanced using a truck mounted hollow-stem auger. Each auger flight is 5 feet in length with an inner diameter of 3.5 inches and an outer diameter of 8 inches. A pilot assembly, in conjunction with the auger head which is fitted with cutting blades, helps advance the auger through the soil and prevents solids from entering the hollow-stem portion of the auger. The hollow auger acts as a "temporary casing" preventing collapse of the borehole wall. Soil cuttings are carried up to the surface via the auger flights.

When the desired sample depth is reached, the drill bit and center plug are removed from the auger stem and replaced with a Modified California Split Spoon sampler. Usually, sampling is done at the end of each 5 foot auger flight. The sampler consists of an outer 12 to 18 inch long "split barrel" sampler in which a thin-walled set of rings is inserted. These rings are brass or stainless steel cylinders, each 2.0 to 3.25 inches in diameter and 3 to 6 inches long.

A 140 pound hammer is used to drive the sampler into the formation below the bottom of the auger flight, thereby filling all of the sampling rings with soil. This method allows for collection of an undisturbed soil sample, preventing introduction of overburden soil by the drilling process. The number of hammer blows (blows per foot, BPF) to advance the sampler a given distance is recorded on the boring log. This gives an indication of the amount of force required to recover the sample.

After retrieving and dismantling the sampler, all the thin tube rings are removed. The bottom ring is immediately sealed for laboratory analysis by covering both ends with teflon sheeting, plastic caps and securing the caps with tape. If some of the soil in the bottom ring has fallen out or appears to have been disturbed during the recovery operation, the second to last ring is used. This ring is labeled and placed in an ice chest for cold storage pending transportation to the laboratory. This packaging protocol is designed to prevent loss of volatiles from the soil sample, and to prevent any cross contamination. Standard chain of custody procedures are followed for all samples.

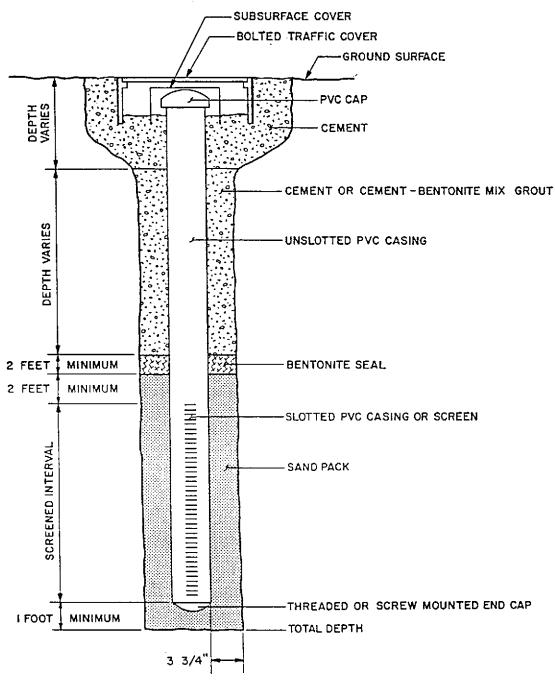

Soil from the second ring is used for field analysis of possible hydrocarbon contamination. The sample is placed in a Ziploc bag, sealed and allowed to volatilize for a HNU Photoionization Analyzer (PID) measurement. A head-space measurement is taken by breaking the seal just enough to insert the probe. The highest reading is recorded. However, if the reading stabilizes at a significantly different level, this also is noted. The PID has a detection range from 0.1 ppm to 2000 ppm for hydrocarbon vapors, when calibrated with a benzene standard.

Soils in the remaining rings are used for the field descriptions. The field data includes a written soils description, the Unified Soil Classification code, and any notable odors, staining or contamination. Also recorded are unusual drilling conditions, equipment malfunctions or other observations of field conditions for future reference. All data are included on the boring logs.

An alternative method to the use of brass rings is glass jars for sample collection. This method still utilizes the split spoon sampler, but no brass rings are inserted. Instead, soil from the base of the sampler is encapsulated in a glass jar. The jar is then treated in the same manner as soil samples in brass rings. The remaining soil in the sampler is used for field analysis and description.

To prevent any cross - contamination, the augers are steam cleaned prior to drilling each boring. The split spoon sampler is cleaned using a three step process commonly referred to as a "three bucket wash". This consist of first a trisodium phosphate wash, followed by a tap water rinse and finally a deionized water rinse. This process is completed between each sample run.

All cuttings and excess sample material recovered during the drilling operations are placed in 55 gallon DOT hazardous waste drums pending laboratory analysis results. Proper disposal is the client's responsibility.

NO SCALE TYPICAL ONLY

TYPICAL MONITORING WELL CONSTRUCTION

- 1. Survey to top of casing from on site reference point for all wells if not already done.
- 2. Put down new polyethelyene sheeting around well.

 Designate a "clean" area for decontaminated equipment and a "dirty" area for equipment already used.
- 3. Measure depth to water and depth to product if present.

 Measure total depth of well with tape. If free product
 is present, collect sample with interface sampler place in vial, label, store.
- 4. Bail 4-5 casing volumes of water with PVC bailer (.163 gallons per foot of depth for 2" wells, .653 gallons per foot with 4" well) discharge into plastic drum. When finished place bailer on "dirty " area to await decontamination procedure. If water is turbid, continue bailing until clean.
- 5. Put on surgical gloves and attach new, clean cord to sampling bailer.
- 6. Rinse sampling bailer and a few feet of the cord with distilled water. Collect sample by lowering bailer into well. Discharge into vial and fill to overflowing. Seal vial, label, place in plastic jar with carbon, seal with security tape, and store in small ice chest.
- 7. Secure well and cover.
- 8. Complete Field Data Sheet and pertinent data on chain of custody sheet.
- 9. Decontaminate water level probe and bailers or pumps with 3 bucket wash and place in clean poly bag.
- 10. Discard poly sheeting, bailer cords, and gloves.

Sample from the cleanest expected well first to the most contaminated well last.

When sample is withdrawn, be aware of any smoke, vapors, etc... from running engines, etc... that may contaminate the sample. Take at least one field blank per station. This is done by pouring laboratory-provided distilled water into a sample vial at the sampling site.

### EQUIPMENT OPERATION AND PROCESS DESCRIPTION

The following is a description of the operation of the RSI S.A.V.E. System. The concepts behind this system are "thermal vacuum spray aeration" and "compressive thermal oxidation". Both of these are well proven concepts. Spray aeration has been proven effective on both large and small scales for the separation of dissolved hydrocarbons and water. The technology for the control of internal combustion engine emissions by using a catalytic converter has also been effectively demonstrated.

The S.A.V.E. System is a blending of three separate types of remediation which is more efficient than the three systems alone. The three systems are as follows:

- 1. Vapor extraction from soil
- 2. Spray aeration treatment of ground water
- 3. Thermal oxidation using an engine for combusting hydrocarbon-laden vapors and a catalytic converter to control the exhaust.

The soil vapor extraction system consists of a vacuum pump driven by the internal combustion engine. The vacuum on the well causes the hydrocarbons to volatilize and flow with the air into the well, up to the vacuum pump, and then to the engine for treatment before discharge.

Ground water contamination is remediated by use of a spray aerator. Spray aeration works on the same principle as an air stripper. In an air stripper, air is moved quickly over the surface of the hydrocarbon-laden water in order to volatilize the laden In spray aeration, hydrocarbon hydrocarbons. droplets move quickly through the air causing the hydrocarbons to volatilize. However, in the spray aerator there is no packing to foul or replace. To ensure sufficient hydrocarbon removal, the water is recirculated through a second set of spray nozzles. this part of the system, water-hydrocarbon separation is enhanced by both vacuum and heat; by lowering the pressure, temperature at which the hydrocarbons vaporize drops. Increasing the temperature further increases the potential for hydrocarbons to vaporize. The RSI spray aerator takes advantage of both of these principles by spraying heated water in a vacuum. The engine provides the energy source for heating the water.

At an assumed recovery rate of 10 gpm total and a circulating rate through the system of 100 gpm there will be an average of 20 cycles through the system before discharge. An 80% - 90% reduction in contaminants per cycle is the normal achieved rate, resulting in final removal rates approaching 100%.

As the water level rises from the influx of water from the wells, a float will trigger a discharge of an equal amount of remediated water. The level of contaminant reduction will be determined by sampling water inputs and discharges from the equipment.

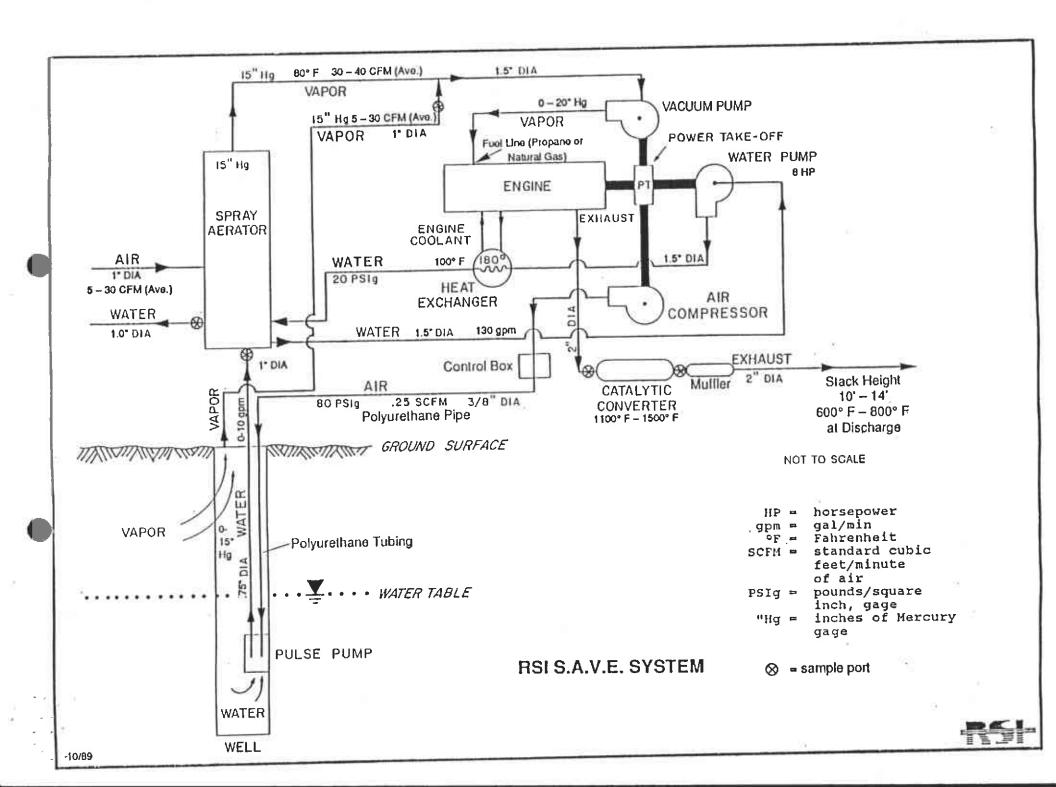

Discharge water will then be passed through activated charcoal for final polishing before discharge.

Hydrocarbons extracted from the water in the spray aerator are combined with the vapors drawn out of the wells. The combined vapors are fed directly to the intake of the engine and after combustion in the engine, the exhaust is passed through a catalytic converter to ensure complete combustion.

The entire system is under vacuum until vapors enter the cylinders of the engine for combustion, so any possible leaks of the seals or connections are into the system, resulting in no loss of hydrocarbons to the atmosphere. If there is no combustion, the engine stops running. Since the engine is the power source for all other equipment, all systems stop when the engine stops, thereby preventing any uncontrolled releases. In addition, the engine will have shut off devices triggered by low oil pressure, loss of vacuum, or engine overheat.

A formal health and safety plan will be prepared for operation of the S.A.V.E. System. To provide for safe and secure operation of this equipment, the following safety elements have been designed into the system:

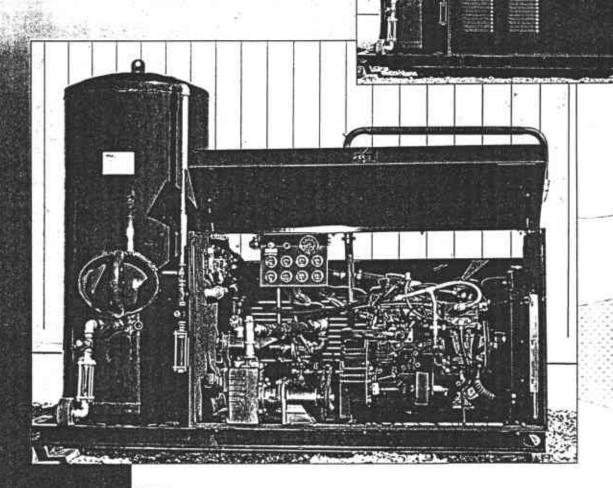

- 1. The engine has automatic features which will turn the entire system off under any of the following conditions:
  - a. Engine overheating
  - b. Recirculating pump pressure dropping below normal range
  - c. Engine oil pressure dropping below normal range.
- 2. The vacuum type fuel pump is mechanically driven by the engine; this ensures that when the engine stops running, all fuel pumping also ceases.
- 3. The hoses connecting the wells to the equipment will run underground through piping.
- 4. All equipment, including the fuel tank, shall be enclosed in a fenced compound, including a fence cover over the top to prevent any tampering with the equipment.

# THE S.A.V.E. SYSTEM

Remediation System for Contaminated Soil and Groundwater

Remediation Equipment • Environmental Services

# THE S.A.V.E. SYSTEM

Spray
Aeration
Vacuum
Extraction

**RSI's** engineered and designed S.A.V.E. system is a cost-effective solution for the separation and destruction of hydrocarbons from contaminated soils and groundwater.

This self contained system is ideally suited for use with monitoring wells at service stations. Designed for ease of installation, operation and maintenance. The system is compact and mobile. It does not need an outside source of power and operates with minimal attendance. A system of gauges and automatic shut-offs prevent engine burnout or needless operation. Negative vapor pressure on the system prevents leakage to atmosphere at valves and connections.

# Security

If security is important, this compact system can be fully enclosed by security fencing with all laterals to wells placed underground.

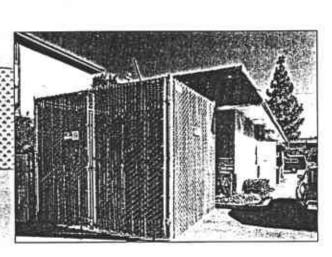

医神经性 经经济公司 计数据记录 医多种性皮肤神经性 医皮肤

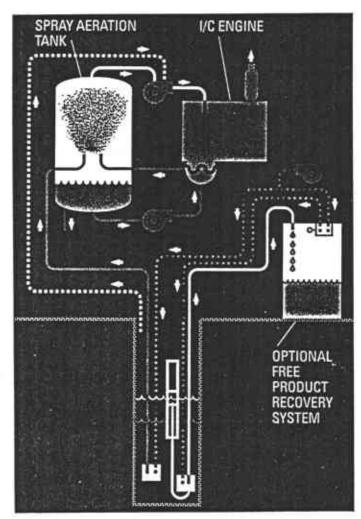

# Operation

Draws water and vapors from monitoring wells.

Separates hydrocarbons from water by volatilization in the spray aeration tank.

Burns up hydrocarbons from water and soil in a small internal combustion engine with catalytic converter.

For Additional Information Please Contact:

#### VAPOR SAMPLING PROTOCOL

#### EQUIPMENT

- Vacuum chamber with fittings.
- 2. 2 liter tedlar bags with valves attached.
  - 3. Two sets of hoses (1 exhaust, 1 intake).
  - 4. Vacuum pump to connect to chamber.

Sampling ports on the equipment consist of female spring loaded quick connect/disconnect fittings. These mate with male fittings on the hoses. The fittings are self sealing and provide complete integrity from sample port to tedlar bag.

#### **PROCEDURE**

Samples are collected by placing a tedlar bag in the vacuum chamber and connecting it to a port on the chamber with a short length of hose. The sample hose is purged with clean air, then connected to the sample port and to the chamber. Using the vacuum pump, air is evacuated from the chamber and vapors are drawn into the tedlar bag. Once the bag is full, the vacuum is released and the bag is allowed to purge back to the source. This procedure is repeated except that when the bag is full it is now sealed before releasing the vacuum.

Subsequent samples are taken using the same procedure. A fresh hose is fitted prior to taking exhaust samples and new hoses are used for each different site. Intake and exhaust samples are kept cool in separate storage containers prior to, and during, transportation to a laboratory for analysis.
