**PHASE III SUBSURFACE INVESTIGATION
MONTGOMERY WARD AUTO SERVICE CENTER
AND
ENEA PROPERTIES SITES
DUBLIN, CALIFORNIA**

1.0 INTRODUCTION

As requested by the Alameda County Health Care Services Agency, Department of Environmental Health (County Health), this document reports the results of the Phase III subsurface investigation activities completed in association with the Montgomery Ward Auto Service Center property, 7575 Dublin Boulevard, Dublin, California (Montgomery Ward Site) and at the Enea Properties Sites located at various addresses on Amador Plaza Road (see Figures 1 and 2). The subsurface investigation was completed to further investigate the lithology and extent of contamination on the sites.

The scope of the Phase III investigation was outlined in the Environmental Audit, Inc (EAI) Work Plan dated May 27, 1994 (see EAI, 1994) and consisted of conducting piezometric cone penetrometer tests (CPT) with pore pressure measurements (designated as CPTu), CPT soil and vapor sampling, and obtaining two Hydropunch ground water samples. Approval to proceed with the work was obtained from Ms. Eva Chu of the County Health in a letter dated June 13, 1994.

2.0 FIELD WORK

Between July 20 and July 21, 1994, eight CPTu soundings (CPT-1 through CPT-7 and CPT-4A) were conducted by Holguin, Fahan & Associates (HFA) under the supervision of EAI geologists at the locations shown on Figure 2. CPTu locations CPT-1, CPT-2, CPT-3, and CPT-6 were placed along the east-west axis of the dissolved hydrocarbon plume. CPT-4, CPT-4A, and CPT-5 were located immediately south and east of the former underground storage tanks (USTs) location, and CPT-7 was located up-gradient of the former USTs location. The depth of the CPTu soundings ranged from approximately 40 to 51 feet below ground surface (bgs). Due to equipment difficulties, the proposed CPTu location in the area of the former fuel island was not completed.

2.1 DEPTH TO GROUND WATER

On July 20, 1994, depth to ground water was measured by EAI staff in selected wells associated with the sites (see Table 1). These wells were gauged in order to determine the depth to ground water for wells in close proximity to the CPTu soundings.

2.2 CONE PENETROMETER TESTING

Procedurally, it was decided that the CPTu soundings would be first completed, followed by vapor and then soil sampling. This procedure was followed due to the fact that fouling of the vapor lines by ground water would occur once the CPTu entered ground water.

The CPTu involved pushing an instrumented cone penetrometer into the soil using a hydraulic/percussion ram assembly pressing against the dead weight of a 20-ton CPT rig. Soil parameters measured at five centimeter intervals include cone penetration resistance or tip resistance (q_c), sleeve frictional stress (f_s), and pore water pressure (see Appendix A). These measurements were transmitted via data transmission cable installed in the hollow CPT rods to an on-board data acquisition system.

Measurement of these parameters typically allows for identification of lithology, and the capillary fringe and ground water table based on the pore water pressures. However, due to the fine grained soils (clays and silty clays), clear identification of the capillary fringe and ground water was not possible with the CPTu data. CPTu data versus depth provide direct and continuous information on subsurface conditions. All data were processed in real time.

Advancement of the cone into the subsurface induces a complex field of stress and strains. The stress values are automatically referenced against an empirical soil classification chart which is part of the CPT computer data analysis package and the stress values are correlated into a soil type. This produces a lithologic log with a resolution of two to five centimeters allowing the interpreted soil classification to be automatically plotted in the field as a function of depth. The CPT system produces a borehole log without requiring sampling or visual inspection. The subsurface conditions encountered in the boreholes are presented in Appendix A and shows the soils encountered are predominantly composed of clay to silty clay.

2.3 PORE PRESSURE DISSIPATION TESTING

Measuring in-situ pore pressures provides information on the distribution of hydraulic head in the area of investigation. Pore pressures are the sum of the in-situ pore pressure and the excess pore pressure that is generated due to penetration of the CPT. Pore pressures are positive in saturated soils, and near zero (or slightly negative) for unsaturated materials. Fine-grained saturated soils exhibit higher pore pressure response than coarse-grained soils because of the difference in permeability. The drainage in coarse-grained deposits is sufficient to dissipate much of the excess pore pressure before it builds up, while fine-grained soils tend to build up a large amount of excess pore pressure. By keeping the probe stationary at a selected depth, pore pressure dissipation tests (PPDTs) can be conducted wherein the excess pore pressure dissipates until eventually only the equilibrium in-situ pore pressure is measured and these equilibrium in-situ pore pressures can be used to determine the hydraulic head at the point of measurement in the water bearing zone investigated.

PPDTs are usually conducted in zones of higher permeability so that equilibrium pore pressures can be reached in a relatively short time, i.e., less than five minutes. However, due to the fine grained nature of the soils encountered at the sites, only eight PPDTs were conducted. These were at location CPT-1 at depths of 18.2 feet, 30.5 feet, 38.9 feet; at location CPT-2 at 26.6 feet and 36.7 feet, and 39.7 feet; at location CPT-4A at 35.4 feet and 39.4 feet; and at location CPT-5 at 39.7 feet (see Appendix B). The duration of the PPDTs ranged from approximately 4 minutes to 22 minutes.

2.4 SOIL VAPOR SAMPLING

Continual downhole sampling of volatile organic vapors as the CPTu probe is advanced into the subsurface was accomplished using two-line vapor sampling design that allows for purging of the vapor collection lines between vapor samples. Purging of the lines

between samples allows continual collection of vapor samples with depth without having to withdraw the line for replacement or purging at the surface, as is the case with single-line samples.

Soil vapor samples were obtained at various depths at locations SV1 through SV3. These vapor sample locations are in close proximity to CPT locations CPT-4, CPT-3, and CPT-5, respectively (see Figure 2). The vapor samples were analyzed with a photoionization detector (ThermoAnalytical OVM, Model 580B). The results are contained in Appendix C.

2.5 SOIL SAMPLING

Soil samples were collected and analytically tested from locations SBCP-1 through SBCP-4 (see Figure 2). The soil samples were obtained from depths ranging between nine and 15 feet bgs. Soil samples were collected with a soil sampling probe mounted onto the end of the CPT rods. The interior of the soil sampling probe is lined with two one-inch outside diameter by three-inch long stainless steel rings. At the designated sampling point, the probe tip is retracted, and the probe is pushed into the undisturbed soil.

After sample recovery, the ends of the lowermost tubes were covered with aluminum foil and plastic caps taped over the ends. Prior to use, all tubes were washed in a solution of Alconox detergent and tap water, rinsed with tap water and then with distilled water. The samples were labeled with the sample point identification, EAI project number, depth interval, time and date, individually sealed in "Ziploc" plastic bags, and immediately placed into an ice chest chilled using crushed ice. The samples were kept chilled until delivered to the laboratory for analytical testing. All samples were logged on chain of custody record forms (see Appendix D).

2.6 GROUND WATER SAMPLING

On July 21, 1994, after completion of the CPTu soundings, two ground water sampling locations (HPCP-1 and HPCP-2) were installed using a QED Environmental HydroPunch II™ (Hydropunch) (see Figure 2). The Hydropunch is a discrete-depth ground water sampling device in which the screen is shielded by a retractable sleeve until the device is seated at a target depth. The sleeve is then retracted which exposes the screen and allows ground water to enter the sampling device.

The ground water sampling locations were selected to attempt to define the down-gradient extent of the dissolved hydrocarbon plume in the easterly direction on the Enea Properties Sites, and the westerly (up-gradient) directions on the Montgomery Ward Site (see Figure 2).

Using the CPT rig, each Hydropunch was pushed to a specified depth. The CPT rods were then retracted about three feet which exposed the screen of the Hydropunch. The base of HPCP-1 was set at approximately 11 feet bgs, and HPCP-2 was set at approximately 16 feet bgs. The depths of the Hydropunches were determined by gauging the fluid levels in still open CPT soundings in close proximity to the Hydropunches (see Table 1). Since ground water seepage into the screen of the Hydropunches was slow and since the CPT holes would stay open (i.e., not collapse upon withdrawal of the CPT rods as evident by other CPT soundings completed at the sites), it was decided that the CPT rods would be withdrawn and the CPT rig would be moved to another location so that field work could be continued. The Hydropunch locations were then secured. After allowing for ground water to fill the Hydropunches, a small diameter Teflon bailer was then lowered into the Hydropunch. A

ground water sample was obtained from HPCP-1 on July 21, 1994 on the day that this Hydropunch was installed. However, there was insufficient seepage of ground water into HPCP-2 for a representative sample to be obtained. Therefore, HPCP-2 was allowed to sit overnight to allow ground water to fill the Hydropunch. On July 22, 1994, a small diameter Teflon bailer was lowered into Hydropunch location HPCP-2. No water sample was obtained from HPCP-2 since an insufficient quantity of water was present in the Hydropunch. HPCP-1 was resampled on July 22, 1994.

The ground water samples obtained on July 21 and 22, 1994 were labeled as described in Section 2.2. The samples were logged on a chain of custody record form (see Appendix D).

2.7 GROUTING OF CPT SOUNDINGS AND SAMPLE HOLES

All CPT sounding and sample holes were grouted by pushing or vibrating a hollow uninstrumented CPT rod with a "knockout plug" down the test hole to termination depth or by dropping bentonite chips into the open hole and hydrating the bentonite. Bentonite grout was pumped into the hole as the CPT rods were being extracted. The holes were filled to within six inches of the surface with bentonite and capped with asphalt or concrete.

2.8 EQUIPMENT CLEANING PROTOCOL

All equipment that was inserted into the ground (rods, screens, cones, etc.) was cleaned between each CPT sounding or Hydropunch. The effluent collected and sealed in labeled 55-gallon drums, pending analytical test results at which time the appropriate disposal method will be determined.

3.0 ANALYTICAL TESTING

All samples were delivered for analytical testing to Sequoia Analytical (Sequoia), a state certified hazardous waste testing laboratory (Certificate #1271) located in Concord, California. The laboratory was instructed to use minimum detection limits for all tests. Sequoia is certified for all testing completed as part of this investigation.

3.1 SOIL SAMPLES

3.1.1 Total Petroleum Hydrocarbons and BTEX Testing

The soil samples collected from the four CPT sounding were tested for total petroleum hydrocarbons as gasoline (TPH-G) using modified EPA Method 8015, and benzene, toluene, ethylbenzene, and ethylbenzene (BTEX) using EPA Method 8020. The results of the testing are shown on Table 2. The laboratory reports are contained in Appendix E.

3.1.2 Soil Leachability Testing

Soil leachability testing was conducted to determine whether the BTEX in the two soil samples obtained during this investigation which contain the highest detected TPH-G concentrations will leach from the soil. The soil leachability testing was conducted using the Toxicity Characteristic Leaching Procedure (TCLP) with deionized water. Use of deionized

water was preferred over a citric acid buffer in order to simulate conditions which most likely will occur under natural conditions, i.e., the leaching effects of downward infiltrating water through soil containing petroleum hydrocarbons.

The results of the modified TCLP testing are contained in Appendix E.

3.2 GROUND WATER SAMPLES

The ground water samples obtained from HCP-1 on July 21 and 22, 1994 were tested for TPH-G and BTEX. The results of the testing are shown on Table 2. The laboratory reports are contained in Appendix E.

4.0 DISCUSSION

4.1 CPT BASED LITHOLOGIES

Exploration of the soils down to approximately 52 feet bgs indicate that the predominant soil types at the sites are clayey silts, silty clays, and clays. Only in CPT-4 and CPT-6 were more coarser soils identified. These coarser soils were only about one foot thick. The low tip resistance (q_c) values indicate that the soils are very soft. These CPT logs closely match the lithology represented on the boring logs previously completed for the sites, and confirms the subsurface conditions encountered at the two sites.

4.2 PPDTs ANALYSES

Analysis of the data obtained from the PPDT testing shows that slow pore pressure dissipation (>5 minutes) was encountered in all of the tests. Several of the tests were terminated prematurely due to extremely slow pore pressure dissipation (i.e., CPT-1 at 30.5 feet, CPT-2 at 26.6 feet, CPT-5 at 39.7 feet, and CPT-4A at 35.4 feet and 39.4 feet).

Based on the PPDT readings, EAI interprets that in-situ pore pressures near or at equilibrium were reached in dissipation tests from CPT-1 at 18.2 feet and at 38.9 feet and CPT-2 at 36.7 feet. These CPTu locations were at the Enea Properties Sites. Converting these pore pressures to hydraulic head equivalents indicates that vertical hydraulic gradients exist within the water bearing zone. The data from CPT-1 at 18.2 feet suggests that a downward vertical gradient of -1.17 feet/feet exist at this location. The data from CPT-1 at 38.9 feet and CPT-2 at 36.7 feet show an upward vertical hydraulic gradient of 1.45 feet/feet and 2.21 feet/feet, respectively.

The PPDTs from the Montgomery Ward Site (CPT-4A and CPT-5) show very slow pore pressure dissipation as compared to CPTs conducted at the Enea Properties Sites. The very slow pore pressure dissipation most likely is the function of differences in the permeability of the soils being measured.

4.3 ANALYTICAL TESTING RESULTS

TPH-G and BTEX were detected in all the soil samples collected except for sample SBCP-1 at 9-9.5 feet. The highest TPH-G concentrations were detected in samples SBCP-1 at 13-13.5 feet (290 milligrams per kilogram [mg/kg]) and SBCP-2 at 13-13.5 feet (230

mg/kg). Sample SBCP-1 at 13-13.5 feet also had the highest concentrations of benzene (2 mg/kg), toluene (6.2 mg/kg), ethylbenzene (7 mg/kg) and xylenes (37 mg/kg) (see Table 2).

The modified TCLP tests using deionized water show that no benzene was detected in the TCLP leachate. Toluene, ethylbenzene, and xylenes, however, were detected in the TCLP leachate, but at very low individual concentrations ranging from 0.016 to 0.56 micrograms/liter (see Appendix E).

No TPH-G or BTEX were detected in the HydroPunch ground water samples collected from Hydropunch location HPCP-1 (see Appendix E).

Soil sample SBCP-1 at 13-13.5 feet was analyzed for total organic carbon (TOC). The results of the testing showed that the sample contained 2,200 mg/kg (0.22 percent) of TOC (see Appendix E).

5.0 LIMITATION

Our professional services have been performed using that degree of care and skill ordinarily exercised, under similar circumstances, by reputable environmental consultants practicing in this or similar localities. No other warranty or representation, expressed or implied, is made as to the professional advice contained in this report.

LCS % Recovery:	99	108	109	112
% Recovery Control Limits:	71-133	72-128	72-130	71-120

Please Note:

The LCS is a control sample of known, interferent free matrix that is analyzed using the same reagents, preparation, and analytical methods employed for the samples. The matrix spike is an aliquot of sample fortified with known quantities of specific compounds and subjected to the entire analytical procedure. If the recovery of analytes from the matrix spike does not fall within specified control limits due to matrix interference, the LCS recovery is to be used to validate the batch.

SEQUOIA ANALYTICAL, #1271

ANALYTICAL REPORT

RECEIVED

AUG - 2 1994

ENVIRONMENTAL AUDIT

Environmental Audit, Inc.
1000-A Ortega Way
Placentia, CA 92670-7125

Date Sampled: 07/22/94
Date Received: 07/23/94
Date Extracted: P/T
Date Analyzed: 07/25/94
Work Order No.: 94-07-337
Method: EPA 8015M
Page 1 of 1

Attn: Frank Muramoto
RE: 1233/Montgomery Ward, Dublin

All total petroleum hydrocarbon concentrations are reported in mg/L (ppm) using gasoline as a standard.

<u>Sample Number</u>	<u>Concentration</u>	<u>Reportable Limit</u>
HPCP-1	ND	0.2
Method Blank	ND	0.2

Reviewed and Approved

on 07/29/1994

ND denotes not detected at indicated reportable limit.

Each sample was received by CEL chilled, intact, and with chain-of-custody attached.
