Re: Semi-Annual Compliance Report
Groundwater and Extraction/Treatment System Monitoring
January through June 2000
FMC Corporation
8787 Enterprise Drive
Newark, California 94560

Dear Dr. Kolb:

By the present letter and the enclosed report, FMC Corporation (FMC) is submitting the "Semi-Annual Compliance Report, Groundwater and Extraction/Treatment System Monitoring, January through June 2000" for the FMC Corporation site located at 8787 Enterprise Drive, Newark, California to the State of California Regional Water quality Control Board, San Francisco Bay Region (RWQCB). This report is being submitted in accordance with Provision C.5. of Site Cleanup Requirements Order Number 98-066, Revision of Site Cleanup Requirements and Recission of Order Number 89-055 for FMC Corporation, 8787 Enterprise Drive, Newark, Alameda County, adopted by the RWQCB on July 15, 1998.

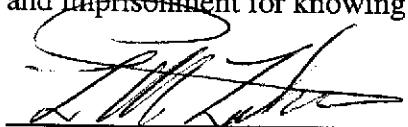

If you have any questions or require further information please contact me at (408) 289-3141.

Semi-Annual Compliance Report
Ground Water and Extraction/Treatment System Monitoring
January through June 2000
FMC Corporation
Newark, California

Dear Ms. Zahiraleslamzadeh:

Enclosed is the semi-annual compliance report on ground water and extraction/treatment system monitoring at the FMC Corporation facility in Newark, California for January through June 2000. The report is submitted in accordance with the requirements of the San Francisco Bay Regional Water Quality Control Board's Order No. 98-066 issued on July 15, 1998. If you have any questions or require additional information, please do not hesitate to call.

Respectfully submitted,

1.0 INTRODUCTION

This report documents ground water and extraction/treatment system monitoring at the FMC Corporation (FMC) facility in Newark, California during the first six months of 2000. Monitoring is performed as part of the overall investigation and remediation of the site, pursuant to Orders No. 98-066, No. 87-49, and No. 85-113 adopted by the California Regional Water Quality Control Board, San Francisco Bay Region (RWQCB). Monitoring activities and reporting requirements were consistent with the revised Self-Monitoring Program (SMP) attached to the most recent RWQCB Order No. 98-066 adopted on July 15, 1998. The remainder of this section presents relevant background information, the objectives of the ground water and extraction/treatment system monitoring program, and the approach to achieving those objectives.

1.1 BACKGROUND INFORMATION

FMC operated a phosphorus chemicals production facility (the site) at 8787 Enterprise Drive in Newark, California. The site location is shown in Figure 1 and a plan of the site is shown in Figure 2. In the past, FMC and predecessor companies also manufactured ethylene dibromide (EDB), a soil fumigant, in the western portion of the site. EDB production ceased and the manufacturing and handling facilities were dismantled and removed in 1968.

Since 1980, a number of investigations have been performed to characterize soil/ground water quality and hydrogeologic conditions at the site and vicinity. The initial investigations focused on delineation of volatile organic compounds (VOCs) in soil and the underlying water-bearing zones and assessment of the ground water flow regime. Recently, FMC has completed a comprehensive site-wide investigation to address all chemicals at the site.

The investigations to date have identified two water-bearing zones within the upper 70 feet of the soil profile beneath the site. The "shallow zone" extends from about 5 to 20 feet

below grade and consists of silty clay and clayey sand. The underlying Newark aquifer extends from about 50 to 70 feet below grade and consists primarily of sand. The two water-bearing zones are separated by the 30-foot thick Newark aquitard.

The principal organic compounds detected in soil and ground water beneath the site are EDB and 1,2-dichloroethane (DCA). These compounds are present in both the shallow zone and the Newark aquifer; however, the concentrations in the Newark aquifer are generally lower than those in the shallow zone. With the concurrence of the RWQCB and California Department of Health Services (DHS), which is now part of the California Environmental Protection Agency (Cal/EPA) Department of Toxic Substances Control (DTSC), most of the previous studies have focused on evaluating EDB in the subsurface environment beneath the site. Throughout the remainder of this report, the area of the site in which EDB is known to be present in soil and/or shallow zone ground water is referred to as the "EDB area." Elemental phosphorus (P_4) is the principal inorganic compound detected in soil in the eastern portion of the site (FMC, July 15, 1999).

In accordance with the waste discharge requirements of RWQCB Order No. 85-113, FMC initiated remedial measures in the Newark aquifer in January 1986. The Newark aquifer remediation program currently involves the extraction of ground water from Wells DW-2 and DW-8 with treatment by granular activated carbon (GAC) to remove dissolved EDB and other organic constituents prior to discharge. With the agencies' concurrence, discharge methods to date have variously included reinjection into the Newark aquifer; surface discharge to the E-1 Ditch; and since October 18, 1988, discharge to a Union Sanitary District (USD) sanitary sewer. The locations of the extraction wells, monitoring wells, the GAC treatment system, and other pertinent surface features are shown in Figure 3. Pursuant to RWQCB Order No. 85-113 and concurrent with the installation of the Newark aquifer remediation program, an asphalt cap with a concrete-lined perimeter drainage ditch was constructed over the area of highest EDB concentrations. The cap and ditch are designed

to minimize the infiltration of precipitation and surface runoff and to control runoff. This area, shown in Figure 3, is referred to as the "capped area."

In accordance with Order No. 87-49 (RWQCB, May 20, 1987), and based on the results of previous investigations, a shallow zone containment system was designed to limit the lateral migration of EDB and remediate shallow zone ground water conditions (Geosystem, December 1987). The shallow zone containment system includes 26 extraction wells, 7 of which (W-33, W-52, W-53, W-55, W-56, W-57, and W-58) have been inactive and recently abandoned (FMC, June 6, 2000) and 2 of which (W-7 and W-54) have been converted to active monitoring wells. The extraction wells are connected to a vacuum pump via a common header. The locations of the shallow zone wells are shown in Figure 3. The extracted water is transferred to the existing GAC units for treatment. The shallow zone containment system has been operating since August 1989.

On July 15, 1998, the RWQCB adopted Order No. 98-066 while recinding Order No. 89-055. Order No. 98-066 requires FMC to complete the remedial investigations and propose final remedial actions with an implementation schedule. The most recent phase of the remedial investigation was performed in accordance with a work plan (FMC, September 25, 1998), which summarized all previous site characterization data and provided the framework and procedures to fully characterize the entire site. The work plan was approved by the RWQCB (November 6, 1998) and Alameda County Water District (ACWD, November 25, 1998) for implementation. On June 15, 1999, FMC submitted the "Remedial Investigation Report" (RI report) to the RWQCB. On September 24, 1999, the RWQCB approved the report subject to certain conditions, which were addressed by FMC in the RI Addendum dated December 9, 1999. As part of the requirements of Order No. 98-066, on December 21, 1999, a human and ecological risk assessment report was submitted by FMC to the RWQCB for review.

To address the evaluation of remedial alternatives and development of cleanup standards, on March 3, 2000, FMC submitted a work plan to the RWQCB to conduct a pilot test in the EDB area using six-phase heating with soil vapor extraction. The RWQCB (April 2000) approved the work plan and FMC is currently implementing the pilot test.

Order No. 98-066 also requires FMC to conduct semi-annual ground water monitoring and reporting. To comply with the requirements of the order, this semi-annual report presents the data collected during the first six months of 2000. The next semi-annual monitoring will be performed in July 2000.

1.2 OBJECTIVES

The overall objective of the ground water and extraction/treatment system monitoring reported herein is to comply with Order No. 98-066 and provide FMC with the data necessary to manage the ground water remediation effort currently underway at the site. Specifically, the monitoring data are intended to facilitate evaluation of the following:

- o The lateral and vertical distribution of VOCs in ground water and the direction/gradient of ground water flow.
- o The effectiveness of the extraction system in containing and remediating VOCs in ground water beneath the site.

1.3 TECHNICAL APPROACH

The technical approach to achieving the stated objectives is based on the requirements of Order 98-066; adherence to standardized monitoring procedures designed to provide reliable, representative, and reproducible data; and evaluation of the data in the context of historic monitoring results and regional ground water quality.

Section 2.0 of this report describes the field activities and laboratory analyses associated with monitoring in the first six months of 2000. Section 3.0 presents an evaluation of

ground water quality conditions and the effectiveness of ground water extraction in achieving hydraulic control and remediating subsurface conditions. The field water quality/sampling records are provided in Appendix A. The historical ground water quality data are presented in Appendix B.

2.0 FIELD ACTIVITIES AND CHEMICAL ANALYSES

Ground water monitoring in the first six months of 2000 was performed in selected wells to evaluate the prevailing ground water flow regime and obtain representative ground water quality data. The field activities were part of a coordinated ground water monitoring program (RWQCB, April 15, 1996) conducted by FMC and neighboring facilities under the direction of the RWQCB. The neighboring facilities include Ashland Chemical Company (Ashland), 37445 Willow Street property (previously known as Romic Environmental Technologies), and Jones-Hamilton Company (Jones-Hamilton). Monitoring consisted of water level measurements, the collection of ground water samples, treatment system monitoring, and chemical analyses. Each of these activities is described in the following sections.

2.1 WATER LEVEL MEASUREMENTS

The depths to ground water in the shallow zone and Newark aquifer wells were measured on January 11 and April 11, 2000 using an electric well sounder. The water levels were measured immediately after accessing each well and prior to any artificial water level disturbance. The measurements were recorded to the nearest 0.01 foot relative to the top of the casing (Tables 1 and 2) in each well. The resulting ground water level data for January and April 2000 monitoring events are summarized in Tables 3 and 4. Tables 3 and 4 also list the water levels in nearby wells as measured by the three neighboring facilities. These water level data were used to generate ground water contours for the shallow zone and Newark aquifer, as described in Section 3.1.

2.2 GROUND WATER SAMPLING

Ground water sampling was conducted between January 11 and 13, 2000 by Geosystem. Sampling activities included well purging; recording of field water quality parameters,

including pH, electrical conductivity (EC), and temperature; and sample collection. These activities are described below.

2.2.1 Well Purging

Prior to sampling, the monitoring wells were purged to remove standing water in the well casings and promote the inflow of representative ground water from the surrounding formation. The monitoring wells were purged using a diaphragm pump.

In accordance with standard sampling procedures, the pH, EC, and temperature of the ground water were measured initially and after the removal of each successive casing volume. Casing volumes were calculated based on the well diameter and the height of the water column in the well casing. The actual volume of water extracted was measured in containers of known capacity. Typically, well purging continued until three casing volumes had been removed from the well or until the well had been pumped dry. The total number of casing volumes purged and the stabilized pH, EC, and temperature measurements are summarized in Table 5. Copies of the field data sheets are included in Appendix A.

The water generated by well purging activities was processed in the existing ground water treatment system and discharged into the USD sanitary sewer.

2.2.2 Sample Collection

On completion of purging and field measurements, ground water samples were collected from each of the monitoring wells using disposable polyethylene bailers. Ground water samples from the Newark aquifer extraction wells were collected at sampling ports located on the discharge piping. The samples were decanted into 40 ml, "zero head-space," glass vials with teflon-lined septa.

As part of the quality assurance/quality control program (QA/QC), two field duplicate samples from Wells W-13 and W-24 (Samples QA/QC-1 and QA/QC-2, respectively), one trip blank sample, and two equipment decontamination blank samples (Samples QA/QC-3 and QA/QC-4) were collected for analysis during the January 2000 monitoring event.

Immediately upon collection, the sample containers were labeled and placed on ice in coolers. For the January 2000 monitoring event, the samples were transported from the site to Columbia Analytical Services (Columbia Analytical) in Santa Clara, California. Standard chain-of-custody procedures were followed at all times from sample collection to delivery to Columbia Analytical.

2.3 TREATMENT SYSTEM MONITORING

Treatment system monitoring in the first six months of 2000 included measurement of the volumes of water extracted and discharged to the USD sanitary sewer and sampling of the treatment system influent and effluent. Maintenance of the treatment system during the first six months of 2000 included the replacement of filter cartridges and changing the carbon in each vessel. The extraction/treatment system operated continuously during the first six months of 2000, except when the system was shut down temporarily for carbon replacement.

Flow volumes are recorded for Newark aquifer Extraction Wells DW-2 and DW-8 via an in-line flow totalizing meter. A second flow meter measures the cumulative influent flow rate for the shallow zone extraction wells. Monthly flow volumes and average extraction rates at these two locations are summarized in Table 6. The total flow volume extracted from the shallow zone during the first six months of 2000 was 357,119 gallons. The corresponding total volumes for Wells DW-2 and DW-8 were 4,045,607 and 1,066,199 gallons, respectively.

Ground water samples from Extraction Wells DW-2 and DW-8 were collected once during January 2000. A grab sample of the combined influent streams, designated as I-1, and the treatment system effluent samples (GT-1) were collected on a monthly basis, for a total of six sampling events during the first six months of 2000.

2.4 CHEMICAL ANALYSES

The ground water and treatment system influent/effluent samples were analyzed for VOCs using U.S. Environmental Protection Agency (EPA) Method 8260. The results of the analyses for detectable concentrations of VOCs in ground water are summarized in Table 7 and discussed in Section 3.2. The concentrations of VOCs in the treatment system influent/effluent samples are summarized in Table 8 and discussed in Section 3.3. The certificates of analyses and chain-of-custody records, as received from Columbia Analytical, are available for review and can be provided upon request. Columbia Analytical is certified by the California Department of Health Services (DHS) for the analyses performed.

3.0 DATA EVALUATION

This section presents an evaluation of the ground water remediation efforts for the first six months of 2000. The ground water hydraulics, ground water quality, performance of the ground water extraction/treatment system, and QA/QC procedures are discussed below.

3.1 HYDRAULIC CONTROL EVALUATION

Ground water level data were used to evaluate the flow regime in the shallow zone and Newark aquifer. The hydraulic response of these water-bearing zones resulting from the ongoing extraction programs at FMC and adjacent facilities are discussed below.

3.1.1 Hydraulic Response in the Shallow Zone

Ground water levels in the shallow zone, as measured by Geosystem and the neighboring facilities, are presented in Tables 3 and 4, respectively. The corresponding ground water contours, shown in Figures 4 and 5, represent pumping conditions at the FMC site during the first six months of 2000. Although water levels in the shallow zone extraction wells are controlled by water level switches and remain below 0 feet mean sea level (MSL) during pumping (Geosystem, April 20, 1990), for contouring purposes, water levels were assumed to be at 1.5 feet and 2.0 feet above MSL for January and April 2000, respectively. Localized ground water depressions are evident in the EDB area as a result of pumping.

Figures 4 and 5 show that the regional flow regime is dominated by ground water extraction from the shallow zone at FMC and the neighboring facilities. Cones of depression are apparent in the vicinity of extraction Wells EW4, J10, and J-4R at the Jones-Hamilton facility in January and April 2000 and around Wells C-2 and B-25 at the Ashland facility in April 2000.

3.1.2 Hydraulic Response in the Newark Aquifer

Ground water levels in the Newark aquifer at FMC and the neighboring facilities for the first six months of 2000 are presented in Tables 3 and 4. As shown in Figures 6 and 7, the ground water contours for the first six months of 2000 demonstrate a westerly flow direction toward the FMC facility. The contours show a cone of depression near FMC Extraction Wells DW-2 and DW-8.

3.2 GROUND WATER QUALITY EVALUATION

The concentrations of VOCs in FMC ground water wells during the first six months of 2000 are summarized in Table 7. To facilitate comparison between current and previous water quality data, a compilation of historical water quality data is presented in Appendix B. Shallow zone and Newark aquifer water quality data are discussed in the following sections.

3.2.1 Shallow Zone Water Quality

The water quality data (Table 7 and Appendix B) indicate that the most prevalent compounds in the shallow zone are bromoform, DCA, and EDB. In addition to these compounds, Wells W-13 and W-20 have shown certain chlorinated VOCs, which are consistent with the historical data. A review of historical data shows that the areal extent of bromoform concentrations has been primarily limited to the area near Monitoring Well W-5 and Extraction Wells W-20 and W-47 through W-50. During the first six months of 2000, the highest bromoform concentrations were detected in Wells W-5, W-36, W-47, and W-48.

Isoconcentrations of DCA and EDB were generated for the FMC site and neighboring facilities from the January 2000 water quality data and are presented in Figures 8 and 9, respectively. DCA has been detected beneath FMC and the neighboring sites, while EDB is present in the western portion of the FMC site.

3.2.2 Newark Aquifer Water Quality

The highest DCA concentration (3,000 $\mu\text{g/l}$) was detected in Well DW-2, located within the capped area. Well DW-8 contained DCA at a concentration of 520 $\mu\text{g/l}$. Other Newark aquifer wells contained significantly lower concentrations of DCA. The DCA isoconcentrations generated from the January 2000 water quality data are shown in Figure 10. The DCA concentrations in the Newark aquifer have decreased since the beginning of the investigations at the FMC site. Review of the historical data shows that EDB concentrations in the Newark aquifer have significantly reduced since investigation began in 1980. The EDB concentrations measured in the Newark aquifer for the first six months of 2000 were below detection limits in all Newark aquifer wells except Extraction Well DW-2 at 120 $\mu\text{g/l}$. The EDB isoconcentrations generated from the January 2000 water quality data are shown in Figure 11. Considering the distribution of DCA and EDB, extraction from FMC's Newark aquifer extraction wells is effective in containing the DCA and EDB plumes.

3.3 TREATMENT SYSTEM EFFICIENCY

The ground water pumping data, presented in Table 6, show that the average flow rate from Wells DW-2 and DW-8 during the first six months of 2000 were 16.4 and 4.3 gpm, respectively. The average extraction rate from the shallow zone for the first six months of 2000 was 1.5 gpm.

The efficiency of the ground water treatment system can be evaluated by comparing system influent and effluent water quality. Table 8 summarizes the treatment system influent and effluent water quality during the first six months of 2000. Samples from Extraction Wells DW-2 and DW-8 were collected and analyzed for VOCs. Table 8 also summarizes the influent water quality (I-1) and the effluent water quality (GT-1), which is monitored after the water has been fully treated by the secondary vessel.

Sampling Station GT-1 represents the final treatment system effluent and is located downstream of the secondary carbon unit. Sampling Station I-1 represents the combined influent from the shallow zone and Newark aquifer immediately upstream of the primary carbon unit. Treatment system influent (I-1) and effluent (GT-1) samples are collected on a monthly basis.

As shown in Table 8, none of the samples collected from Sampling Station GT-1 contained detectable concentrations of any VOCs. Overall, the GAC unit has been effective in removing VOCs from the influent stream.

The estimated mass of EDB and DCA removed each year and for the first six months of 2000 from ground water is presented in Table 9. Utilizing the total flow rates and average influent concentrations, approximately 35 pounds of EDB and 110 pounds of DCA were removed by the treatment system in the first six months of 2000. Since ground water extraction began in 1986, approximately 914 pounds of EDB and 4,474 pounds of DCA have been removed. Table 9 shows a general reduction in mass removal rates attributable mostly to the decrease in concentrations, particularly from 1986 to 1991.

3.4 QUALITY ASSURANCE/QUALITY CONTROL MEASURES

Several QA/QC measures were implemented to provide qualitative and quantitative checks on data quality. Field QA/QC measures included duplicate samples from Wells W-13 and W-24, identified as QA/QC-1 and QA/QC-2, respectively; one trip blank sample; and two equipment decontamination blank samples designated as QA/QC-3 and QA/QC-4. The samples identified as QA/QC-3 and QA/QC-4 consisted of water collected through the purge hoses from Wells W-13 and W-21, respectively, subsequent to decontamination. Laboratory QA/QC measures included laboratory control samples (LCS) and QC blank, matrix spike, and duplicate analyses. The results of these QA/QC measures are discussed below.

3.4.1 Blank Sample Analyses

Blank samples analyzed as part of the overall QA/QC program included trip, method, and equipment decontamination blank samples. The trip blank sample and the method blank samples analyzed by Columbia Analytical using EPA Method 8260 did not contain detectable concentrations of VOCs. The equipment decontamination blank samples (QA/QC-3 and QA/Q-4) consisted of FMC's municipal water supply run through hoses from the vacuum extraction pump after being used for purging Wells W-13 and W-21. The equipment decontamination blank sample QA/QC-3 contained 1.4 $\mu\text{g/l}$ of chloroform and 1.5 $\mu\text{g/l}$ of TCE. Equipment decontamination blank sample QA/QC-4 contained 2.4 $\mu\text{g/l}$ of chloroform and 3.1 $\mu\text{g/l}$ of 1,2-DCA.

3.4.2 Data Precision

Data precision may be defined as a measure of mutual agreement among individual similar conditions. For the FMC project, data precision was evaluated by the analysis of field duplicate samples and expressed in terms of percentage difference. Field duplicates are samples collected in the field, from the same source, using identical sampling procedures, and submitted "blind" to the laboratory. The field duplicates are analyzed by the same laboratory using standard EPA analytical methods. As shown in Table 10, the precision for the field duplicates ranged from 3.2 to 116 percent.

3.4.3 Data Accuracy

Data accuracy may be defined as the degree of agreement of a measurement with an accepted reference or true value. Data accuracy is evaluated by the analysis of laboratory control samples and matrix QC samples. The calculated percentage recovery of the spiking compound is taken as a measure of the accuracy of the total analytical method. The tolerance limits for acceptable percent recovery vary according to the analytical method and the spike compound(s). The data indicate that the percent recovery calculated for various compounds were within laboratory control requirements.

3.4.4 Data Validity

Data validity is assessed by quantitatively evaluating data precision and accuracy and by qualitatively evaluating the results of blank sample analyses. The results of the QA/QC measures obtained from the trip blank sample, method blank samples, and decontamination blank samples showed an acceptable degree of accuracy. Also, the ground water quality data are generally consistent with the historical data and, thus, are considered valid. However, the January 2000 water quality data reported for Well W-23 are not consistent with the historical data and should not be considered valid. In accordance with the RWQCB's request, a summary of the sampling QA/QC and a summary of the analytical QA/QC are presented in Tables 11 and 12, respectively.

3.5 SUMMARY OF COMPLETED AND PROJECTED ACTIVITIES

During the first six months of 2000, the following activities pertaining to investigation/remediation of the FMC site were performed:

- o Ground water level measurements in January and April 2000.
- o Ground water sampling in January 2000.
- o Submission of the "Annual Compliance Report - 1999" to RWQCB in January 2000.
- o Preparation of pilot test work plan for six-phase heating and soil vapor extraction (FMC, March 3, 2000).
- o Startup of the pilot test for six-phase heating with soil vapor extraction in May 2000.
- o Treatment system influent and effluent monitoring.
- o Routine maintenance of the extraction/treatment system.
- o Submission of quarterly reports to USD.

- o Abandonment of Extraction Wells W-33, W-52, W-53, W-55, W-56, and W-57 in April 2000.
- o Submission of the report on extraction well abandonment (FMC, June 6, 2000).

The following activities are planned for the second six months of 2000:

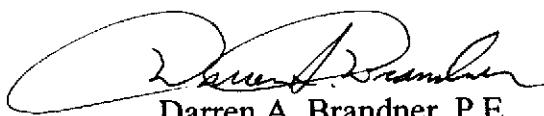

- o Conduct activities in accordance with RWQCB Order No. 98-066.
- o Ground water monitoring scheduled for July 2000.
- o Ground water level measurements scheduled for October 2000.
- o Treatment system influent and effluent monitoring.
- o Change of carbon in the GAC vessels, as required.
- o Quarterly progress reports to be submitted to USD.
- o Routine maintenance of the ground water remediation system.
- o Present the results of the six-phase heating/soil vapor extraction pilot test.
- o Submit the report on "Proposed Final Remedial Actions and Cleanup Standards."

Other unanticipated activities pertaining to subsurface investigation/remediation will be reported as appropriate.

Respectfully submitted,

GEOSYSTEM CONSULTANTS, INC.

Mohsen Mehran, Ph.D.
Project Manager
(CGWP No. 189)

Darren A. Brandner, P.E.
Senior Engineer
(RCE No. C 048849)

NOTES: (1) DW-2 refers to influent concentration of ground water extracted from one Newark aquifer well;

DW-8 refers to influent concentration of ground water extracted from one Newark aquifer well;

I-1 represents a composite of DW-2, DW-8 and shallow zone.

GT-1 refers to effluent concentration from the second carbon unit.

(2) The symbol "<" denotes the concentration was "less than" the analytical limit shown.

NOTE: (1) Flow totals from 1989 were used for calculations, as no flow data were available.

(2) January through June 2000.

(3) Shallow zone concentration calculated as follows:

$$Conc_{sz} = \frac{(Flow_{total} * Conc_{l-1}) - (Flow_{DW-2} * Conc_{DW-2}) - (Flow_{DW-8} * Conc_{DW-8})}{Flow_{sz}}$$

TABLE 10

**DATA PRECISION
FIELD DUPLICATES
EPA METHOD 8260
JANUARY THROUGH JUNE 2000**

<u>SAMPLE</u>	<u>COMPOUND</u>	<u>ORIGINAL ANALYSIS</u> ($\mu\text{g/l}$)	<u>DUPPLICATE ANALYSIS⁽¹⁾</u> ($\mu\text{g/l}$)	<u>PERCENTAGE DIFFERENCE⁽²⁾</u>
W-13	1,1,2-Trichlorotrifluoroethane (CFC 113)	39	73	61
	1,1-Dichloroethene (1,1-DCE)	8	30	116
	Tetrachloroethene (PCE)	19	29	42
	Trichloroethene (TCE)	190	200	5.1
W-24	1,2-Dichloroethane (1,2-DCA)	40	43	7.2
	Trichloroethene (TCE)	3.2	3.1	3.2

NOTES: (1) Field duplicate samples identified to Columbia Analytical as QA/QC-1 and QA/QC-2 for Wells W-13 and W-24, respectively.

(2) Percentage difference calculated as:

$$\frac{\pm 2(D_1 - D_2)}{(D_1 + D_2)} * 100$$

where D_1 = Original analysis and
 D_2 = Duplicate analysis
